38 **ABSTRACT**

39 The aim of this review was to systematically assess and meta-analyze the effects of low
40 FODMAP diet (LFD) on severity of symptoms, quality of life and safety in patients with
41 irritable bowel syndrome (IBS). The databases MEDLINE/PubMed, Scopus and the
42 Cochrane Library were screened through 19th January 2016. Randomized controlled trials
43 (RCTs) comparing LFD to other diets were included when assessed symptoms of IBS or
44 abdominal pain in patients with IBS. Safety, quality of life, anxiety, depression and effect on
45 gut microbiota were defined as secondary outcomes. Standardized mean differences (SMD)
46 and 95% confidence intervals (CI) were calculated. Nine RCTs with a total of 596 subjects
47 were included. Three RCTs compared LFD to habitual diet, two RCTs provided all meals and
48 compared LFD to western diet, one RCT each compared LFD to a diet high in FODMAPs or
49 a sham diet and two RCTs to other diet recommendations for IBS. Meta-analysis revealed
50 significant group differences for LFD compared to other diets on gastrointestinal symptoms
51 (SMD=-0.62; 95%CI=-0.93 to -0.31; p=0.0001), abdominal pain (SMD=-0.50; 95%CI=-0.77 to
52 -0.22; p=0.008) and on health-related quality of life (SMD=0.36; 95%CI=0.10 to 0.62;
53 p=0.007). Three studies reported a significant reduction in luminal Bifidobacteria after LFD.
54 Adverse events were assessed in three RCTs only, no intervention-related adverse events
55 were reported.
56 Finally, this meta-analysis found evidence for short-term efficacy and safety of LFD in
57 patients with irritable bowel syndrome. However only preliminary recommendation for LFD
58 can be made until long term effects are investigated.

59

60 **Keywords:** Irritable Bowel Syndrome, FODMAP diet, gut microbiota, Meta-analysis

61 **BACKGROUND**

62 Irritable bowel syndrome (IBS) describes a group of symptoms that include abdominal pain
63 or discomfort, and changes in bowel movement patterns and defecation. Although correlation
64 between pathophysiology and symptoms is lacking for most cases, patients experience
65 abdominal pain and a negative impact on quality of life. IBS is the most common functional
66 gastrointestinal (GI) [1] and diagnosis of IBS is based on Rome criteria [2].

67 Although nearly 60 % of patients claim that certain foods trigger their symptoms, IBS patients
68 who eliminate those foods, often only find minor symptom improvements [3]. A novel
69 treatment option for IBS is the low Fermentable, Oligo-, Di-, Mono-saccharides and Polyol
70 (FODMAP) diet which focuses on the restriction of fermentable, short-chain carbohydrates,
71 including galacto- and fructo-oligosaccharides (GOS, FOS), lactose (disaccharide), fructose
72 (monosaccharide) and sorbitol (polyol). These carbohydrates are poorly absorbed in the
73 small intestine which leads to an increased intestinal osmolality and causes gas production
74 due to their rapid fermentation and osmotic action [4]. Therefore, the mechanism behind the
75 low FODMAP diet lies in reducing the fermentable load and liquid volume delivered to the
76 colon, to reduce gas production and luminal distension associated with gastrointestinal
77 symptom relief in IBS patients [5]. Primary purpose of this study is to review and meta-
78 analyze the effectiveness of such a diet in the treatment of functional gastrointestinal
79 symptoms in IBS patients, while the secondary goal is to determine the safety of the
80 treatment and the influence on the microbiome.

81

82 **METHODS**

83 PRISMA guidelines for systematic reviews and meta-analyses [6] and the recommendations
84 of the Cochrane Collaboration [7] were followed.

85

86 **Eligibility criteria**

87 Types of studies

88 Randomized controlled trials (RCTs) and randomized cross-over studies were eligible.

89 Types of participants

90 Adults, adolescents and children with irritable bowel syndrome were eligible if they were
91 diagnosed by Rome Criteria [8]. Studies involving participants with comorbid physical or
92 mental disorders were eligible for inclusion.

93 Types of interventions

94 *Experimental*

95 Dietary interventions including the application of a low FODMAP diet were eligible. No
96 restrictions were made regarding duration of the program. Studies with co-interventions were
97 allowed.

98 *Control*

99 Habitual diet or standard dietary intervention.

100 Types of outcome measures

101 To be eligible, RCTs had to assess at least one primary outcome:

102 1. Severity of IBS-symptoms, measured by patient-rated scales, such as the Irritable Bowel
103 Syndrome – Severity Scoring System (IBS-SSS) [9], or any other validated scale.

104 2. Abdominal pain or discomfort measured through means such as a Numeric Rating Scale
105 (NRS).

106 Secondary outcomes included:

107 1. Quality of life or well-being measured by any generic or disease-specific validated scale
108 such as the (SF-36) [10] or (IBS-QOL) [11].

109 2. Anxiety or depression measured by any validated scale such as Hospital Anxiety and
110 Depression Scale (HADS) [12].

111 3. Analysis of gut microbiota.

112 4. Safety of the intervention assessed as number of patients with adverse events.

113

114 **Search methods**

115 MEDLINE/PubMed, Scopus and the Cochrane Library, databases were searched from their
116 inception through 19th January 2017. The literature search was constructed around search
117 terms for “FODMAP” or “fermentable oligosaccharides disaccharides monosaccharides and
118 polyols” and search terms for “irritable bowel syndrome” or “IBS”. For PubMed, the following
119 search strategy was used: (*“Irritable Bowel Syndrome”[MeSH] OR “Irritable bowel
120 syndrome”[Title/Abstract] OR “IBS”[Title/Abstract]*) AND (*“FODMAP”[Title/Abstract] OR
121 “FODMAPS”[Title/Abstract] OR “fermentable oligosaccharides disaccharides
122 monosaccharides and polyols”[Title/Abstract]*) AND (*“Randomized Controlled
123 Trial”[Publication Type] OR “controlled clinical trial”[Publication Type] OR
124 randomized[Title/Abstract] OR placebo[Title/Abstract] OR random[Title/Abstract] OR
125 randomly[Title/Abstract] OR trial[Title/Abstract] OR group[Title/Abstract]*). The search
126 strategy was adapted for each database as necessary.

127 Abstracts identified during literature search were screened and potentially eligible articles
128 were read in full to determine whether they met eligibility criteria.

129

130 **Data extraction and management**

131 Data on patients (e.g. age, diagnosis), methods (e.g. randomization, allocation concealment),
132 interventions (e.g. duration, administration of diet, dietary adherence), control interventions
133 (e.g. type, co-interventions, outcomes (e.g. outcome measures, assessment time points) and
134 results were extracted independently by two authors using an a-priori developed data

135 extraction form. Discrepancies were discussed with a third review author until consensus
136 was reached. If necessary, the study authors were contacted for additional information.

137

138 **Risk of bias in individual studies**

139 Two authors independently assessed risk of bias using the risk of bias tool proposed by the
140 Cochrane Collaboration [7]. This tool assesses risk of bias on the following domains:
141 selection bias, performance bias, attrition bias, reporting bias, and detection bias using 12
142 criteria. Risk of bias was assessed for each criterion as 1) low risk of bias, 2) unclear, 3) high
143 risk of bias. Discrepancies were discussed with a third review author until consensus was
144 reached.

145

146 **Data analysis**

147 Assessment of effect size

148 If at least 2 studies assessing a specific outcome were available, meta-analyses were
149 conducted using Review Manager 5 software (Version 5.1, The Nordic Cochrane Centre,
150 Copenhagen) by a random effects model [10] using the generic inverse variance method. For
151 continuous outcomes, standardized mean differences (SMDs) with 95% confidence intervals
152 (CIs) were calculated as the difference in means between groups divided by the pooled
153 standard deviation (SD). SMDs were calculated as Hedge's g using a standardized Excel
154 spreadsheet. For dependent samples (ie, crossover trials), the calculation was adapted for
155 intercorrelations between groups. Where no correlation was reported, it was estimated as
156 0.7. Where no SDs were available, they were calculated from standard errors, CIs, or t -
157 values, or attempts were made to obtain the missing data from the trial authors by e-mail. A
158 negative SMD was defined to indicate beneficial effects of the low FODMAP diet compared
159 with the control intervention for all outcomes (eg, decreased gastrointestinal symptoms)
160 except for quality of life where a positive SMD was defined to indicate beneficial effects (ie,
161 increased quality of life). Cohen's categories were used to evaluate the magnitude of the
162 overall effect size as follows: SMD of 0.2 to 0.5, small; SMD of 0.5 to 0.8, medium; and SMD
163 greater than 0.8, large effect sizes.

164

165 Assessment of heterogeneity

166 The I^2 statistics, a measure of how much variance between studies can be attributed to
167 differences between studies rather than chance, was used to analyze statistical
168 heterogeneity between studies. The magnitude of heterogeneity was categorized as $I^2=0$ -
169 25%: low heterogeneity; $I^2=26$ -50%: moderate heterogeneity; $I^2=51$ -75%: substantial
170 heterogeneity; and $I^2=76$ -100%: considerable heterogeneity.[7, 13] The χ^2 test was used to
171 assess whether differences in results were compatible with chance alone. Given the low

172 power of this test when only few studies or studies with low sample size are included in a
173 meta-analysis, a P-value ≤ 0.10 was regarded to indicate significant heterogeneity [7].

174

175 Sensitivity analyses

176 To test the robustness of significant results, sensitivity analyses were conducted for studies
177 with high versus low risk of bias at the following domains: selection bias (random sequence
178 generation and allocation concealment), detection bias (blinding of outcome assessment),
179 and attrition bias (incomplete outcome data). If present in the respective meta-analysis,
180 subgroup and sensitivity analyses were also used to explore possible reasons for statistical
181 heterogeneity.

182

183 RESULTS

184 Literature search

185 The literature search retrieved 179 records, of which 113 non-duplicate records were
186 screened and 105 records were excluded because they did not use a RCT design and/or low
187 FODMAP diet was not an intervention. One further RCT was excluded as it used the low
188 FODMAP diet only to wash-out symptoms in the initial stage of the investigation on the
189 effects of diets high or low in gluten [14]. Nine full-text articles (RCTs) with a total of 596
190 subjects were finally included for qualitative analysis [15-23]. One randomized cross-over
191 trial was excluded from quantitative synthesis as data was not displayed as mean and SD
192 and further information from the authors could not be retrieved [24]. Of those, 561 patients
193 matched the intervention criteria and were included in the meta-analysis (Figure 1).

194

195 Study characteristics

196 Characteristics of the sample, interventions, outcome assessment and results are shown in
197 Table 1.

198

199 Setting and participant characteristics

200 Of the 9 RCTs that were included, 1 originated from Australia [17], 1 from New Zealand [22],
201 2 from USA [16, 23], 1 from Canada,[18] and 4 from Europe [15, 19-21]. Patients were
202 recruited from gastroenterology clinics [15, 18, 20, 22, 23], internet announcements and/or
203 advertisement in newspapers [15-17, 22, 23], private dietetics and tertiary pediatric
204 gastroenterological care [16]. Patients in all RCTs were diagnosed with IBS according to
205 Rome-III criteria, including subtypes with predominant symptoms of either diarrhea or
206 constipation, mixed/alternating symptoms or of unspecified type (IBS-D, IBS-C, IBS-M/A,
207 IBS-U), except for 2 RCTs that only included IBS-D and/or symptoms of bloating [20, 23].
208 Patients' age ranged from 7 years to 83 years with a median age of 39.5 years. Between

209 67% and 86% (median: 71.0 %) of patients in each study were female. McIntosh et al. [18]
210 and Eswaran et al. [23] were the only studies to specify further exclusion criteria such as the
211 use of antibiotics, intake of probiotics, stool bulking agents, narcotic analgesic and lactulose.
212 Patients were also excluded if on Paleolithic or gluten-free diet, low FODMAP or low
213 carbohydrate diet.

214

215 **Intervention characteristics**

216 Two RCTs compared LFD to habitual diet [20, 22], one RCT compared it to a diet generally
217 recommended for IBS [15] and two studies provided all meals and compared LFD to western
218 diet (American/Australian) [16, 17]. One study compared LFD to a diet high in FODMAPs [18]
219 and one trial compared it to a sham diet [21]. One RCTs measured LFD up to usual diet
220 recommendations for IBS [15] and one RCT compared the LFD to modified NICE guidelines
221 [23]. In the 7 interventions that did not provide meals, dietary advice was given by an
222 experienced dietician.

223

224 **Outcome measures**

225 Symptoms of IBS were assessed in all RCTs for gastrointestinal symptoms and pain using
226 Likert Scale [16], Visual Analogue Scale [14, 17], Numeric Rating Scale [23], GI Symptom
227 Rating Scale [20, 21], Adequate Relief Question [23] or Irritable Bowel Syndrome – Severity
228 Scoring System (IBS-SSS) [15, 18, 19, 21, 22]. Quality of life was assessed in 2 studies
229 using the Irritable Bowel Syndrome Quality of Life (IBS-QOL) questionnaire [19, 21, 22].
230 Anxiety was assessed in 2 RCTs using the Hospital Anxiety and Depression Scale (anxiety
231 subscale, HADS-A) [16] and the Visceral Sensitivity Index (VSI). Depression was assessed
232 through Hospital Anxiety and Depression Scale (depression subscale, HADS-D) in 1 RCT
233 [16]. While all RCTs reported short-term effects, no RCT reported long-term effects. Stool
234 microbiota composition was analyzed by 16S rRNA gene profiling by 4 studies [16, 18, 20,
235 21].

236

237 **Risk of bias in individual studies**

238 Risk of bias in individual studies is shown in figure 2. All studies reported adequate random
239 sequence generation, but five studies [15-17, 22, 23] did not report sufficient allocation
240 concealment and none of the studies used/reported adequate blinding of participants and
241 personnel. Blinding of outcome assessment was sufficient in three studies [18, 21, 23]. Low
242 risk was assessed for incomplete outcome data in all but one RCT [16]. Three RCTs were of
243 high risk [16, 17, 23] for suspected selective reporting. High risk had also to be considered
244 concerning other bias in two studies [22, 23].

245

246 **Analysis of overall effect**

247 Results of the meta-analysis are displayed in figures 3-5.

248 Primary outcomes

249 The meta-analysis revealed significant group differences for LFD compared to any control on
250 gastrointestinal symptoms (SMD=-0.62; 95%CI=-0.93 to -0.31; p=0.0001; heterogeneity:
251 $I^2=77\%$; $\text{Chi}^2=29.95$; P 0.0004), and abdominal pain (SMD=-0.50; 95%CI=-0.77 to -0.22;
252 p=0.008; heterogeneity: $I^2=63\%$; $\text{Chi}^2=19.07$; P 0.0004).

253 While one study found no difference between IBS-D and IBS-C patients [17], improvements
254 in IBS symptoms were less for patients with IBS-C in two studies [15, 19]. Investigating
255 mainly IBS-C subtypes, Chumpitazi et al. identified only 8 responders to the LFD out of 33
256 participants [16] while subjects of the remaining studies were primarily of IBS-D or IBS-M
257 type [15, 18, 20-23].

258

259 Secondary outcomes

260 Evidence was found for short-term effects of LFD compared to any control on health-related
261 quality of life (SMD=0.36; 95%CI=0.10 to 0.62; p=0.007; heterogeneity: $I^2=14\%$; $\text{Chi}^2=3.48$; P
262 0.32). One RCT measured anxiety and depression with the HADS questionnaire, but no
263 significant differences were found in between groups.

264 Four of the included RCTs assessed gut bacteria via 16SrRNA-profiling. Staudacher et al.
265 demonstrated a reduction in concentration and proportion of luminal Bifidobacteria after 4
266 weeks of LFD [20, 21] but not when combined with probiotics [21]. In accordance, McIntosh
267 et al. found a decrease in Bifidobacteria after LFD. Chumpitazi et al. solely assessed
268 microbiota at baseline to identify potential responders and non-responders to the LFD
269 according to individual gut bacteria profiles and found responders to be enriched in microbes
270 from several taxa with a larger saccharolytic potential.

271

272 Safety

273 Three studies provided safety-related data, assessed by adverse events [16, 20, 23].
274 Chumpitazi et al. and Eswaran et al. reported the absence of adverse events [16, 23].
275 Staudacher et al. reported four adverse events, two in the intervention group (bronchitis,
276 laryngitis) and two in the control group (exacerbation of asthma, pharyngitis) [20]. None of
277 these were considered related to the intervention.

278

279 **Sensitivity analysis**

280 Results for gastrointestinal symptoms and abdominal pain did not change when only RCTs
281 with low risk of selection bias, detection bias, or attrition bias were included; the effects were
282 thus judged to be robust against potential methodological bias. Effects for quality of life were

283 robust against selection and attrition bias, but did not remain significant in sensitivity
284 analyses for detection bias. Assessment of publication bias was initially planned using funnel
285 plots generated by Review Manager software; however, as fewer than 10 studies were
286 included in each meta-analysis, funnel plots could not be analysed.

287

288 **DISCUSSION**

289 **Summary of evidence**

290 In this systematic review of nine randomized trials significant evidence for short-term benefits
291 of diets low in FODMAPs was found for gastrointestinal symptoms, abdominal pain and
292 quality of life in patients with irritable bowel syndrome, while no side effects were reported.
293 Effects were robust against potential methodological bias.

294 Despite the evidence supporting LFD efficacy, more than 25% of IBS subjects do not
295 improve on the diet [25]. This meta-analysis shows that adherence to LFD significantly
296 improves gastrointestinal symptoms. However, these improvements were investigated mostly
297 for patients with diarrhea predominant IBS type [15, 19]. Symptom relief for diarrhea-type IBS
298 is supposed to be due to osmotic changes. Constipation underlies different intestinal
299 mechanisms and has been associated with a lack of dietary fiber, although additional
300 fiber intake seems to be only moderately effective in idiopathic constipation [26]. The LFD
301 has been criticized for not providing sufficient sources of fiber, and further research is
302 required to look into effects on single subtypes as well as conjunctive therapies benefitting
303 constipation-type IBS. A strong association of psychiatric disorders in 94% of IBS patients
304 could be found [27, 28] and further studies should investigate anxiety and depression as
305 secondary outcomes.

306 One of the presumed mediators of the efficacy of a diet low in FODMAPs is the gut
307 microbiome [25] which is also suggested to be involved in the etiology of IBS and depression
308 [29, 30]. The potential benefits of Bifidobacteria in IBS has been indicated [31, 32] and
309 patients with IBS may have lower concentrations of luminal and mucosal Bifidobacteria [33].
310 As the LFD seems to lower gut Bifidobacteria, further research should focus on this outcome.

311

312 **Agreements with prior systematic reviews**

313 Only one prior systematic review has assessed the effects of a low FODMAP diet in IBS so
314 far. This review limited its assessment on two instruments, the IBS-SSS Symptom severity
315 Score and the IBS-QOL for IBS quality of life, and included 6 RCTs as well as 16 non-
316 randomized trials [34]. In line with our more comprehensive review, this prior review found a
317 significant decrease in IBS-SSS score and improvement in IBS-QOL score in both RCTs and
318 non-randomized interventions. The findings of our review are also in line with a descriptive
319 review on LFD for IBS which considered 40 articles (31 original studies and 9 reviews) and

320 concluded that the LFD should be the first dietary approach in patients with IBS as they
321 found it not only improve symptoms but also to provide relative ease of implementation [35].

322

323 **External and internal validity**

324 All studies used Rome criteria as a standard for eligibility, thus standardizing the results.
325 Overall, risk of bias of the included studies was unclear. Only three studies reported
326 adequate blinding of outcome assessment [18, 21] and a general high risk was found for
327 performance bias. Mainly patients from Europe, Australia, New Zealand and from North
328 America were included and female patients represented the majority of participants, thus the
329 findings might be limited to geographical regions and might not be fully applicable to male
330 patients [36].

331

332 **Strengths and weaknesses**

333 Strengths of this review include the comprehensive literature search and the assessment of
334 applicability of the results [37]. The primary limitation of this review is the limited overall
335 sample size and the methodological heterogeneity of the studies. Further, none of the
336 studies reported long-term effects, results of this review cannot be extrapolated for long term
337 effects. Results concerning gastrointestinal symptoms are based solely on subjective self-
338 reported outcomes. It has to be considered, that the IBS-SSS may fail to detect changes in
339 patients with mild IBS scoring lower than 175 [9]. Most importantly, safety of the intervention
340 was insufficiently reported. Two unpublished studies were included which are according to
341 the study coordinators in the process of submitting for publication. The usefulness of
342 including unpublished trials is still under debate [7].

343

344 **Implications for further research**

345 Further trials should develop programs that agree on an effective duration for gastrointestinal
346 symptom relief, suggested by the majority of research to occur within the first week of
347 adherence. While these effects seem to be due to osmotic changes, a stable adaption of gut
348 microbiota to dietary changes is suggested to take more time [38]. For a more detailed IBS
349 symptom assessment, the IBS Severity Scoring System is preferable and the IBS Quality of
350 Life measurement scale can be used to establish changes in health-related quality of life
351 [39]. Another drawback of this review resulted from partly insufficient reporting of trial
352 methodology, and authors of prospect research should improve the reporting of trials and
353 follow commonly accepted reporting guidelines (e.g. CONSORT) [40]. Moreover, it is
354 essential for further trials to survey dietary adherence, which is a driving factor for symptom
355 relief. The LFD requires intensive meal planning by the patients. In contrast to study

356 interventions, the daily supply of patients with precooked meals is not feasible in terms of
 357 time and costs in regular clinical practice.

358

359 CONCLUSION

360 This meta-analysis found evidence that the low-FODMAP diet is effective to relieve
 361 symptoms, and to improve quality of life in patients with irritable bowel syndrome. Still, long-
 362 term outcomes and safety of low-FODMAP diets remain to be investigated. Further studies
 363 are required to evaluate its long term effects on gut microbiota, cost effectiveness and
 364 efficacy as compared to other modalities.

Table 1: Characteristics of the included studies.

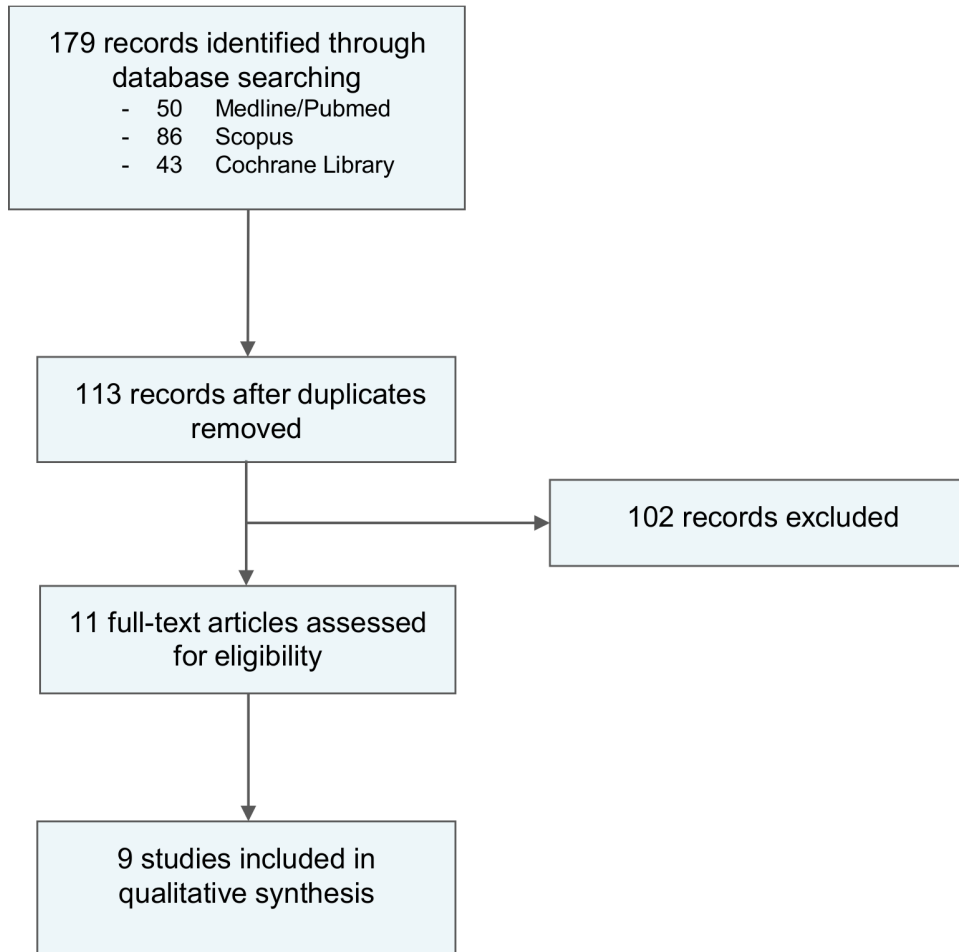

Reference	Origin	Sample	Intervention	Control group	Follow up	Outcome measures	Results
	Country	Sample size; mean age; gender; ethnicity; diagnostic criteria	Intervention; program length; study design	Intervention; program length;	Outcome assessment	<ol style="list-style-type: none"> 1. GI symptoms 2. Abdominal pain 3. Life Quality 4. Anxiety 5. Depression 6. Safety 	Low FODMAP diet compared to control group:
Böhn et al., 2015	Sweden	Sample size: n=75 (intervention n=38, control n=37) Age: 18-69; (42.5) Gender: 31 f Ethnicity: NR Diagnostic criteria: Rome III, all subtypes	Low FODMAP diet (3.8 ± 3.3 g/d) 4 weeks Dietary advice Single blind parallel design	Diet usually recommended for IBS (13.5 ± 8.7 g/d) 4 weeks Dietary advice	4 weeks	<ol style="list-style-type: none"> 1. IBS-SSS 2. IBS-SSS subscale 3. NA 4. VSI 5. NA 6. NR 	The severity of IBS symptoms was reduced in both groups without a significant difference between the groups. Food diaries demonstrated a good adherence to the dietary advice. 8 patients dropped out prematurely during the intervention period. Reporting of adverse events was lacking.
Chumpitazi et al. 2015	USA	Sample size: n=52 (intervention n=16; control n=17) Age: 7-17 (mean NR) Gender: 22 f Ethnicity: NR Diagnostic criteria: Rome III	Low FODMAP diet (max. 9 g/d) 48 h Meals provided Double-blind crossover	Typical American childhood diet (TACD) (max. 50 g/d) 48 h	48 h	<ol style="list-style-type: none"> 1. Likert Scale 2. Likert Scale 3. NA 4. HADS-A 5. HADS-D 6. Adverse events 	During LFD, significantly less abdominal pain occurred vs. the TACD diet. The total composite GI score was significantly lower on LFD vs. TACD. Compliance between both diets was similar. 19 children dropped out of the study, 74% left the study prior to the start of any intervention. Adverse events did not occur.
Eswaran et al. 2016	USA	Sample size: n=92 (intervention n=50 control n=42) Age: 19-75 (mean 42.6) Gender: 65 f Ethnicity: 74% caucasian Diagnostic criteria: Rome III, IBS-D	Low FODMAP diet 4 weeks Dietary advice Single blind parallel design	mNICE guidelines 4 weeks Dietary advice	4 weeks	<ol style="list-style-type: none"> 1. Adequate relief, Bristol stool scale 2. NRS 3. NA 4. NA 5. NA 6. Adverse events 	The LFD group had a significantly lower intake in FODMAPs after 4 weeks. There was no significant differences between the groups for the Adequate Relief. Significant difference in favor of the LFD group occurred for abdominal pain and stool consistency. 7 patients left the study prematurely (LFD: 5, mNICE: 2). No adverse events occurred as reported by the investigators.

Halmos et al., 2014	Australia	<i>Sample size:</i> n=33 (crossover design) <i>Age:</i> 29-53 (41.0) <i>Gender:</i> 21 f <i>Ethnicity:</i> NR <i>Diagnostic criteria:</i> Rome III, all subtypes	Low FODMAP diet (Ø 3.1 g/d) 21 days meals provided single blind cross-over	normal western (australian) diet, (Ø 23.7 g/d) 21 days meals provided	21 days, wash-out at least 21 days	1. VAS 2. VAS 3. NA 4. NA 5. NA 6. NA 7. NA	IBS patients had lower overall GI symptoms and pain scores while on a low FODMAP diet compared to a western Australian diet. 3 participants exited the study before commencing the second diet. Adverse events were not assessed.
Harvie et al. 2015	New Zealand	<i>Sample size:</i> n=50 (intervention n=23; control n=27) <i>Age:</i> 20-66 (41.8) <i>Gender:</i> 43 f <i>Ethnicity:</i> 96 % caucasian <i>Diagnostic criteria:</i> Rome III, subtypes IBS-D, IBS-C, IBS-M	Low FODMAP diet 3 months FODMAP content: 10.0 ± 7.9 g/d Dietary advise Unblinded Parallel design	Usual diet 3 months FODMAP content: 27.1 ± 15.6 g/d waitlist	3 months	1. IBS-SSS 2. IBS-SSS subscale 3. IBS-QOL 4. NA 5. NA 6. NR	A significant relationship between a change in FODMAP content and a reduction in symptom severity could be shown. There was also a tendency towards a change in total FODMAP content and a change in IBS Quality of life. 4 patients dropped out prematurely. Reporting of adverse events was lacking.
McIntosh et al., 2016	Canada	<i>Sample size:</i> n=40 (intervention n=20; control n=20) <i>Age:</i> 24-83 (50.9) <i>Gender:</i> 32 f <i>Ethnicity:</i> NR <i>Diagnostic criteria:</i> Rome III, all subtypes	Low FODMAP diet 3 weeks Dietary advise, booklet with sample meals Single blind parallel design	High FODMAP diet 3 weeks Dietary advise, booklet with sample meals	3 weeks	1. IBS-SSS 2. IBS-SSS subscale 3. NA 4. NA 5. NA 6. NR	Comparison of the IBS-SSS post diet scores showed a significant reduction in the low compared to the high FODMAP group for gastrointestinal symptoms and abdominal pain. Compliance with the diets was good. Reporting of adverse events was lacking.
Pedersen et al., 2014	Denmark	<i>Sample size:</i> n=127 (LFD n=23; probiotic n=41; control n=13) <i>Age:</i> 18-73 (34.6) <i>Gender:</i> 90 f <i>Ethnicity:</i> NR <i>Diagnostic criteria:</i> Rome III, subtypes IBS-D, IBS-C, IBS-A	Low FODMAP diet 6 weeks Dietary advice Unblinded parallel design	1. normal western (danish) diet (habitual diet) 2. probiotic supplementation with 2 capsules Lactobacillus rhamnosus GG daily (6 billion per capsule) 6 weeks	6 weeks	1. IBS-SSS 2. IBS-SSS subscale 3. IBS-QOL 4. NA 5. NA 6. NR	Statistically significant reduction in IBS-SSS score in the LFD group compared to normal diet. No significant effects in the probiotics group compared to normal diet. 8 patients discontinued participation from the low FODMAP diet, 3 from the normal diet and 4 from the probiotics group. A report of adverse events was missing.

Staudacher et al., 2012	UK	<i>Sample size:</i> n=41 (intervention n=23; control n=13) <i>Age:</i> Range NR (34.6) <i>Gender:</i> 27 f <i>Ethnicity:</i> NR <i>Diagnostic criteria:</i> Rome III, IBS-D	Low FODMAP diet (Ø 17.7 g/d) 4 weeks Dietary counselling by the same experienced dietician Weekly contact via email or phone 7 day food diary at baseline and final week Unblinded parallel design	Habitual diet (Ø 29.6 g/d) 4 weeks	4 weeks	1. Validated GI Symptom Rating Scale, Global Symptom Question 2. 4-Point Subscale of the Symptom Rating Scale 3. NA 4. NA 5. NA 6. Adverse Events	Significantly more patients in the intervention group reported adequate symptom control and lower incidence of abdominal pain compared to control group. Patients in the intervention group had a significant reduction in scores for overall symptoms compared to control. Six patients dropped out of the study. Four patients had adverse events (two in the intervention, two in the control group) none of which were related to the trial.
Staudacher et al., 2016	UK	<i>Sample size:</i> n=104 (intervention n=51; control n=53) <i>Age:</i> Range NR (34.4) <i>Gender:</i> 70 f <i>Ethnicity:</i> 86 caucasian <i>Diagnostic criteria:</i> Rome III, IBS-D, IBS-M, IBS-U	Low FODMAP diet 4 weeks Dietary advise Unblinded parallel design	Sham diet 4 weeks Dietary advise	4 weeks	1. IBS-SSS, GSRS 2. IBS-SSS subscale 3. IBS-QOL 4. NA 5. NA 6. NR	LFD resulted in a significantly lower IBS-SSS score than sham diet after intention to treat analysis, and more patients on the LFD achieved the 14-point minimal clinical important difference for IBS-QOL scores. Reporting of adverse events was lacking.

Legend: d – day; f - female; GI – Gastrointestinal; GIS - Global Improvement Scale; HADS-A - Hospital Anxiety and Depression Scale (anxiety related); HADS-D - Hospital Anxiety and Depression Scale (depression related); IBS-D – diarrhea predominant IBS; IBS-GAI - IBS Global Assessment of Improvement; IBS-QOL – Irritable Bowel Syndrome Quality of Life questionnaire; IBS-SSS - IBS Symptom Severity Scale; LFD – Low FODMAP diet; m - male; mNICE – modified guidelines from the National Institute for Health and Care Excellence; NA - not assessed; NR - not reported; NRS - Numeric Rating Scale; VAS – Visual Analogue Scale; VSI - The visceral sensitivity index; TACD - Typical American childhood diet
