Abstract

Recently, there have been some breakthroughs in graph analysis by applying the graph neu-5 ral networks (GNNs) following a neighborhood aggregation scheme, which demonstrate 6 outstanding performance in many tasks. However, we observe that the parameters of the 7 network and the embedding of nodes are represented in real-valued matrices in existing 8 GNN-based graph embedding approaches which may limit the efficiency and scalability 9 of these models. It is well-known that binary vector is usually much more space and time 10 efficient than the real-valued vector. This motivates us to develop a binarized graph neural 11 network to learn the binary representations of the nodes with binary network parameters fol-12 lowing the GNN-based paradigm. Our proposed method can be seamlessly integrated into 13 the existing GNN-based embedding approaches to binarize the model parameters and learn 14 the compact embedding. Extensive experiments indicate that the proposed binarized graph 15 neural network, namely BGN, is orders of magnitude more efficient in terms of both time 16 and space while matching the state-of-the-art performance. 17

1 Introduction

Graph analysis provides powerful insights into how to unlock the value graphs hold. Due 20 to this power, techniques for analyzing graphs are becoming an increasingly popular topic 21 of study in both academics and industry. To effectively and efficiently support important 22 analytic tasks on graph data, such as node/graph classification, node clustering, community 23 detection, node recommendation, link prediction and graph visualization, a variety of graph 24 embedding techniques (See [5, 11] for a comprehensive survey) have been developed. Graph 25 data is mapped into low-dimension data such that the proximity relationship among graph 26 nodes (i.e., objects) is preserved and the off-the-shelf machine learning methods, which are 27 designed to handle vector representations, can be immediately applied. 28

Extended author information available on the last page of the article.

The existing graph embedding techniques can be roughly classified into three broad cat-29 egories: (1) random walk based embedding (e.g., Deepwalk [26] and Node2vec [9]); (2) 30 31 node similarity based embedding (e.g., LINE [38] and NetMF [30]); and (3) graph neural networks (GNN) based embedding (e.g., GCN [15], GraphSage [10], GAT [40] and AS-32 GCN [12]). As reported by Leskovec et al. in their tutorial on graph embedding at WWW 33 2018¹, the first two categories of embedding techniques are only able to learn a "shallow" 34 representation of the graph nodes due to the simplicity of the models. It is shown in [10, 35 15] that the neural network based embedding methods significantly outperform the state-36 of-the-art techniques in the first two categories for the node classification task. Therefore, 37 exploring how to use neural network to create a "deep" representation more efficiently is a 38 promising direction in graph representation learning. However, most of the existing graph 39 neural network models suffer from the scalability issue due to the high time and space cost 40 of the real-valued model. 41

42 Recently, there have been some researches on learning binary graph embedding (e.g., [20, 43 37, 46]), in which each node is represented by a binary vector (code), instead of a real-valued 44 vector. It has been shown that the binarized graph embedding can achieve much better time 45 and space efficiency.

46 Time efficiency. It is well-known that the distance computation of binary vectors (i.e., 47 Hamming distance) is much more efficient than that of real-valued vectors (e.g., Euclid-48 ian distance). In addition to the specifically tailored search algorithms (e.g., [29]), the 49 dot product between binary vectors can also enjoy the hardware support (e.g., *xnor* and 50 build-in CPU instruction *popcount*).

- As stressed in a recent work [18] from *DeepMind*, the pairwise dot product of the vectors has been intensively used by the model for some specific tasks (e.g., graph similarity computation in [1]). Thus, the binary vector has been used in their graph matching network (GMN) to speedup the computation.
- 55 Space Efficiency. The binary embedding can represent the node in a compact way while
 56 well preserving the structure information. As shown in [20], INH-MF can achieve com57 petitive graph node classification performance with 128 bits for each node compared
 58 to the conventional embedding approaches (e.g., DeepWalk) with 128 dimensions (i.e.,
 59 128 × 64 bits) per node. This will be a great advantage when we face a large-scale graph
 60 because the binarized embedding of a graph is more likely to be accommodated in the
- 61 main memory.
- Motivation and Challenges. The existing GNN-based methods have demonstrated outstanding performance in various tasks such as classification [10, 12, 15, 40], link prediction [14, 48], graph similarity match [1, 18] and graph clustering [41, 49]. However, they may suffer from the limitation of the memory and speed due to the use of real-valued vectors for node and graph representations and model parameters.
- 67 Given the outstanding embedding quality, various applications of the GNN-based 68 approaches and the space and time efficiency of the binarized representation, one may 69 wonder if we can design a binarized GNN-based graph embedding approach such that 70 we can achieve a good trade-off between embedding quality and time/space efficiency in 71 the GNN-based methods.
- We notice that the existing binarized graph embedding methods [20, 37] rely on the discretization of the matrix factorization following the node-similarity based approaches.

¹http://snap.stanford.edu/proj/embeddings-www

World Wide Web

They cannot be extended to binarize the GNN-based embedding due to the inherently 74 different natures of two categories of approaches. 75

As to our best knowledge, the only attempt for the binarization of GNN is from 76 *DeepMind* in their recent work [18]. Their binarization method converts each learned d-77 dimensional real-valued vector into a *d*-dimensional "nearly" binary vector by applying 78 well-known binarization function *tanh* to approximate hamming distance for the bina-79 rization and optimization. However, the output of tanh is not exact binary value and 80 cannot be accelerated by the binary logic operations (e.g., xnor and popcount). As an 81 alternative, one may consider the Binarized Neural Network (BNN) (e.g., [13]) for the 82 graph embedding so that the representation is naturally binarized. However, BNN is 83 not designed for graph data, and as to our best knowledge, there is no existing graph 84 embedding work based on BNN. 85

These issues motivate us to develop a new binarized graph embedding technique which86can be integrated into existing GNN-based models to binarize the parameters and produce87high-quality binarized graph embeddings. The key challenge is how to generate effective way. To88address the challenge, we design a binarized graph neural network framework to learn90the binary parameters and representations efficiently and effectively .91

Contributions. Our principle contributions are summarized as follows:

- To the best of our knowledge, this is the first study on binarized graph neural network (GNN) with binary parameters to generate binary graph representations. The proposed method, namely BGN, can be seamlessly integrated into the existing GNNs.
- An end-to-end binarized graph neural network framework is proposed with binary 96 weights and activations. This binarized framework can immediately reduce the memory consumption for the network; the bit-wise operations between the binary vectors 98 can substantially speedup the inference time of the model and the gradient estimator 99 enables our model to effectively process back-propagation through discrete parameters 100 and activations.
- Extensive experiments on multiple benchmark networks are conducted for node classification task. The results demonstrate that our proposed method outperforms existing binarized embedding methods with a big margin. Compare to the real-valued GNNs, our BGN model can achieve nearly state-of-the-art performance while consuming much fewer computation resources (up to 1/28 parameter and embedding memory space and 1/20 inference time).
- Binarization approaches are employed on the GNN-based application GMN to show that, by applying our BGN techniques, GMN model can dramatically reduce the time and space complexity while keeping the performance competitiveness.
- Experiments further show that our proposed BGN technique allows users to achieve a trade-off between the space/time and embedding quality in a flexible way by tuning different level and setting of binarization on the parameters and activations.

Graph Embedding. A key problem in machine learning on graphs is finding a way to incorporate information about the structure of the graph into the desired machine learn-

ing model. Graph embedding is one of the most promising approaches because it maps 117 nodes into a low-dimensional space such that the structure of the graph is well preserved. 118 Once accomplished, an existing machine learning approach (e.g., k-means clustering) 119 can be used to assimilate and analyse the graph in the embedded low-dimensional space. 120 Loosely following the seminal graph embedding approach, DeepWalk, three broad cate-121 gories of embedding methods have appeared in the literature: (1) node similarity based 122 embedding methods (e.g., LINE, NetMF), which rely on the proximity of the nodes w.r.t 123 various similarity metrics. The matrix factorization techniques have been used to learn 124 the embedding of the nodes. (2) Random walk based embedding methods (e.g., Deep-125 walk and node2vec) which encode the nodes by applying the Skip-Gram technique [25] 126 on the random walks; and (3) graph neural networks (GNN) based embedding methods 127 (e.g., GCN, GraphSage and GIN) [10, 12, 15, 40, 42, 45] which apply the neural network 128 techniques on graph to learn the representations of the nodes. 129

Most of the existing graph embedding studies use the real-valued vector to encode 130 the graph nodes following the above three computing paradigms. Recently, three unsu-131 pervised approaches [20, 37, 46] have been proposed to learn the *binary embedding* of 132 the graphs following the node-similarity based embedding methods. Particularly, INH-133 MF [20] and DNE [37] are independently developed for binarized graph embedding 134 135 based on the discretization of the matrix factorization on proximity graphs. BANE proposed in [46] is a natural extension of DNE by considering both structure and attribute 136 similarities on the attributed graphs. 137

- **Binary Hashing.** The binary hashing has been widely used to learn the binary vectors 138 (codes) of the objects in many applications. The most popular application is the approx-139 imate nearest neighbor search in high dimension space where binary hashing methods 140 encode high-dimensional objects (e.g., documents and images) to binary codes, while 141 preserving similarity distance in the original space. Many learning to hash approaches 142 have been proposed including unsupervised methods (e.g., [22, 33]), supervised meth-143 ods (e.g., [35]), and deep learning based methods (e.g., [21]). Please refer to [43] for a 144 comprehensive survey. Recently, three approaches [20, 37, 46] have been proposed to 145 learn the binary embedding of the graphs following the node-similarity based embed-146 ding methods. As to our best knowledge, there is no existing work on the binarized graph 147 embedding based on GNNs. 148
- Binarized Neural Networks Binarized neural networks (see [27] for comprehensive survey) was first proposed by BNN [4]. The binarization technique proposed in [4] is
 used by most network binarization models. Among them, XNOR-Net [31] and DoReFaNet [50] are the most popular ones because of their great performance on the image classification task.
- 154 XNOR-Net was proposed to have high accuracy of classification task on the ImageNet 155 dataset while XNOR-Net has $58 \times$ faster convolutional operations and $32 \times$ memory 156 saving. DoReFa-Net replaces the binarization by quantization which allows the model 157 to change the bit size for weights, activations and even gradient calculations during 158 backpropagation.
- Recently, more binarized neural networks [3, 17, 23, 24, 28, 36, 47] and low bitwidth neural networks [8, 51] are proposed to further reduce the time cost of performing the machine learning model and apply these networks on the devices with low computation resources.

World Wide Web

However, these methods are all designed for computer vision tasks. Though they perform well on the image dataset, they cannot be adapted to the graph representation learning and graph analysis task directly.

Graph Neural Network ApplicationsThere are several applications that are based on
the GNN. Such as Graph Matching Network [18] and SimGNN [1]. These models utilize
GNN and use the similarity (distance) of graph embedding to approximate the graph edit
distance and graph similarity.166169169

The Graph Matching Network (i.e., GMN) is a novel GNN-based framework proposed 170 by *DeepMind* to compute the similarity score between input pairs of graphs. Separate MLPs 171 will first map the input nodes in the graphs into vector space. Then the propagation layer 172 will aggregate the messages of the edges and cross-graph matching vector by MLP or GRU 173 with input concatenation of node representations and edge vectors. Matching function is 174 applied to compute the attention coefficients based on the node information between the 175 input pair of graphs. The matching function is based on the softmax function over node 176 vectors which requires the calculation of vector space similarity like Euclidean, cosine sim-177 ilarity or dot product between all pairs of node representations. This attention coefficients 178 calculation across two graphs requires a computation cost of $\mathcal{O}(|V_1||V_2|d)$, where 179 V_1 and V_2 indicate the number of vertices of input graph 1 and 2 respectively, and d is 180 the dimension of the node representation. The match vector $\mu_{i \to i}$ is concatenated with the 181 message vector $\mathbf{m}_{i \to i}$ and the node representation $\mathbf{h}_{i}^{(t)}$, then the concatenation is fed into 182 MLP or a recurrent neural network core to produce the new node representations. Given 183 the learned node representations of graph, the aggregation module proposed in [19] is used 184 to obtain the graph representations. The similarity score in vector space such as Euclidean 185 similarity, cosine similarity and approximate hamming similarity will be computed between 186 graph representations to approximate the similarity between the input graphs. 187

3 Background and preliminaries

Recent studies have revealed that graph neural network can perform excellently on label 189 classification tasks. The existing GNN-based graph embedding approaches share the same 190 computing paradigm. GNNs take graph nodes' feature and neighborhood information as 191 the input. During the training, the representations of nodes (real-valued vectors) at each 192 layer will be updated by the aggregators and non-linear activation functions. The output 193 representations will be fed into the task-specific layer to calculate the loss of the model. 194 Based on that, the model will be optimized by the optimizer through backpropagation. The 195 main differences among these GNN-based graph embedding approaches are the design of 196 the aggregator which combines the context representations and the loss function designed 197 for different graph analytic tasks. 198

These models have real-valued parameters and learn a real-valued representation for 199 each node in an end-to-end manner for graph node classification. However, the real-valued 200 parameters and representations are space-consuming for storage and time-consuming for 201 multiplication computation, especially for large-scale graphs. To address these issues, in this 202 paper we devise a novel binarized graph neural network, namely BGN, with binary parameters in the neural network to learn binary embedding representations for node classification 204 task. 205

The important notations used throughout the paper are summarized in Table 1.

207 4 Binarized graph neural network

As illustrated in Figure 1, we introduce a new graph neural network with binarized weights 208 and activations. Our model BGN (Binarized Graph Neural Network) is based on the atten-209 tion mechanism and can be easily adapted into other graph neural network frameworks. For 210 a given graph, BGN takes the nodes and their contexts including feature and neighborhood 211 structure information as input. Binarization function will transform the weights, activations 212 and even coefficients into binarized vectors to reduce the time and space complexity, while 213 the attention mechanism enables the nodes to attend over their neighborhoods' features. We 214 also apply the balance function to ensure that +1 and -1 are almost equal with each other 215 in the binarized vectors. Furthermore, the gradient estimator is used for backpropagation of 216 gradients through discretization. 217

- The following subsections present the listed key components of our model:
- 219 Section 4.1 introduces the **framework** of our work.

- (\mathbf{X}) : XNOR and popcount operation between binary-valued tensors.
- (\underline{S}) : Masked summation between binary-valued and real-valued tensors.
- + : Concatenation of the vectors.

Algorithm 1 illustrates the framework of our model. We follow the attention mechanism 227 introduced in [39, 40] to involve the *importance* of the node's neighborhoods into the graph 228 representation learning process. Given a graph $G(\mathcal{V}, E)$, where \mathcal{V} and E denote the set of 229 graph nodes and edges respectively, we use nodes features $\{\mathbf{x}_v, \forall v \in \mathcal{V}\}, \mathbf{x}_v \in \mathbb{R}^m$ and the 230 neighborhood information of nodes $\{\eta_v, \forall v \in \mathcal{V}\}$ as inputs. *Balance*(·) denotes the balance 231 function which is introduced in Section 4.4.3. Our model will first produce the binarized 232 node representations $\mathbf{h}_{v}^{b} \in \{+1, -1\}^{d}$ for each node within the input graph. After that, the 233 binarized node embeddings will be fed into the output layer to compute the loss for some 234 specific tasks like node classification. 235

Algorithm 1 Binarized graph neural network.

Input: Graph $G(\mathcal{V}, E)$, node features $\{\mathbf{x}_v, \forall v \in \mathcal{V}\}$, number of layers *L*, binarization function $\mathcal{B}(\cdot)$, number of attention heads *K*, neighbors of node $\{\eta_v, \forall v \in \mathcal{V}\}$ **Output**: Classification result $\{\mathbf{C}_v, \forall v \in \mathcal{V}\}$

1: Let $\mathbf{h}_{v}^{0} = \mathbf{x}_{v}, \forall v \in \mathcal{V}, \forall u \in \eta_{v};$ 2: for $l = 1, 2, \ldots, L - 1$ do $\alpha_{uv}^{l} = \mathcal{B}(Softmax_{v}(\mathbf{W}_{0}^{l}\mathbf{x}_{u}, \mathbf{W}_{0}^{l}\mathbf{x}_{v}))$ 3: for $v \in \mathcal{V}$ do 4: for $k \in K$ do 5: $\mathbf{h}_{v}^{k} = \mathcal{B}(\sum_{u \in \eta_{v}} Balance(\alpha_{uv}^{k} \mathbf{W}_{k}^{l} \mathbf{x}_{u}));$ 6: $\mathbf{h}_{v}^{l} = Concat_{k=1}^{K}(\mathbf{h}_{v}^{k})$ 7: 8: $\alpha_{uv}^L = \mathcal{B}(Softmax_v(\mathbf{W}_0^L \mathbf{h}_u^{L-1}, \mathbf{W}_0^L \mathbf{h}_v^{L-1}))$ 9: for $v \in \mathcal{V}$ do 10: $\mathbf{C}_{v} = Softmax(\sum_{u \in n_{v}} \alpha_{uv}^{k} \mathbf{W}^{L} \mathbf{h}_{u}^{L-1})$ 10: 11: **return** \mathbf{C}_v , the classification result for node $v \in \mathcal{V}$

237

236

Attention Mechanism Our proposed framework is based on the graph attention mechanism. The attention layer is utilized in our model to learn the importance of every node to other nodes. The key is to get the *importance* of one node's feature to other nodes that is the attention coefficients of the input graph, afterwards, the node's feature can attend on other nodes. Inspired by [40], we perform *masked attention* to the model to keep the structural information of the input graph. Only the attention coefficients of one node with its neighborhood nodes i.e., $\alpha_{ij}, v_j \in \eta_i$ will be computed.

In order to obtain the attention coefficients, we use a shared **binarized** weight matrix $\mathbf{W} \in \{+1, -1\}^{m \times d'}$ to apply the linear transformation to each node. Softmax function is 246

used to normalize the coefficients, but unlike the model proposed in [40], LeakyRelu activation is not employed in our model while the sign function is used to binarize the attention coefficients. With the following (1), we will get a **binarized** attention coefficient matrix $\mathcal{A} \in \{+1, 0, -1\}^{N \times N}$ where α_{ij} is the element of the matrix \mathcal{A} (0 is contained in the matrix since we only compute the attention coefficients between neighbors such that the matrix is sparse).

$$\alpha_{ii} = \mathcal{B}'(Softmax_i(\mathbf{W}\mathbf{x}_i, \mathbf{W}\mathbf{x}_i)) \tag{1}$$

where \mathcal{B}' is the binarization function for attention coefficients which maps 0 to 0, positive values to +1 and negative values to -1.

Once the attention coefficient matrix is obtained, it will be used to compute the output of the attention layer. The attention coefficients will multiply the linear transformed node feature. We employ the *multi-head attention mechanism* to stabilize the learning process. The binarization function, which is served as an activation function, is applied to every attention head to binarize the pre-activations. And concatenation of the output of K independent attention head is the output of the attention layer. Therefore, the output node representation will be like following:

$$\mathbf{h}_{i} = \|_{k=1}^{K} \mathcal{B}(\sum_{j \in \eta_{i}} \alpha_{ij}^{k} \mathbf{W}^{k} \mathbf{x}_{j})$$
(2)

Where \parallel means the concatenation of the vectors and \mathbf{h}_i is the output **binarized** node representation where $\mathbf{h}_i \in \{+1, -1\}^d$.

After several attention layers, the node representation will be fed into the last layer to calculate the loss for specific task which is classification in this paper. We will introduce the learning objective in the Section 4.3.

267 4.2 Binarization

In this section, we introduce how to obtain a graph neural network with binary parameters that can learn binary representations. Section 4.2.1 introduces the binarization function used to transform the real-valued parameters and pre-activations into binary space. Section 4.2.2 introduces the gradient estimators that enable the binarized model to be optimized by the

272 off-the-shelf optimizers such as Adam and SGD.

273 4.2.1 Forward propagation

274 Binarization function is important in our model. Specific binarization function will be chosen in the forward propagation calculation process to binarize the weights and the 275 activations. In that way the low-bit parameters and activations will help to reduce the 276 277 time and space complexity. In our case, various binarization functions will work, and the most straightforward example is the sign function. As mentioned in [4] and [31], 278 deterministic and stochastic binarization based sign function are widely applied to the con-279 tinuous pre-activations as well as the real-valued weights to obtain binarized activations and 280 weights. 281

$$\mathcal{B}_{det}(x) = \begin{cases} +1 \ x \ge 0, \\ -1 \ else, \end{cases}$$
(3)

The above equation is the deterministic binarization function, where x is the real-valued variable. The stochastic binarization is the sign function with probability:

$$\mathcal{B}_{stoch}(x) = \begin{cases} +1 \text{ with probability } p = \sigma(x), \\ -1 \text{ with probability } 1 - p, \end{cases}$$
(4)

🖄 Springer

World Wide Web

AUTHOR'S PROOF

where σ denotes the sigmoid function, that is $\sigma(x) = 1/(1 + exp(-x))$. The stochastic 284 binarization is more appealing but needs the computer to generates random bits while the 285 deterministic binarization is easier to calculate. Deterministic binarization function(i.e., (3)) 286 is applied for the binarization of weights and activations because the deterministic sign 287 function provides more stable and reproducible results. Please note that we use a variant of 288 deterministic sign function which maps 0 to 0 to binarize the attention coefficients. 289

Other than directly binarize the weights in the graph neural network, we follow the quantization process in [31] to add a scaling factor $\gamma \in \mathcal{R}^+$ to estimate a real-valued weights such that $W \approx \gamma B$, thus achieve better performance. We can find the optimal quantizer by minimizing the quantization error: 293

$$\min \mathcal{J}(\gamma \mathbf{B}) = \|\mathbf{W} - \gamma \mathbf{B}\|^2 \tag{5}$$

According to results and analysis in [31], for each real-valued weight W, the optimized binary matrix B^* and scaling factor γ^* can be obtained by the following constrained optimization: 296

$$B^* = \underset{B}{\operatorname{arg\,min}} W^T B \tag{6}$$

$$\gamma^* = \frac{W^T B^*}{n} = \frac{1}{n} \|W\|_{\mathcal{L}^1}$$
(7)

where **B** is constrained to be a binarized matrix, *n* is the number of elements within the 298 weight **W**, if $W \in \mathbb{R}^{m \times d}$, then $n = m \times d$.

Furthermore, we also adopt the Libra Parameter Binarization (LPB) introduced in IRnet [28] to retain the information and minimize the information loss in forward propagation by jointly considering both quantization error and information loss. LPB also quantify the real-valued weight W using a scaling factor such that $W \approx \gamma B$. Suppose each element in B can be viewed as a sample of random variable obeying Bernoulli distribution shown in (4). The entropy of the quantization in the following (8) is also considered as a part of loss function: 306

$$\mathcal{H}(\gamma \mathbf{B}) = \mathcal{H}(\mathbf{B}) = -p \ln(p) - (1-p) \ln(1-p)$$
(8)

Together with the quantization loss described in (5), the objective function of LPB is defined 307 as: 308

$$\min \mathcal{J}(\gamma \mathbf{B}) - \lambda \mathcal{H}(\gamma \mathbf{B}) \tag{9}$$

We further apply the standardization and balance described in [28]. As a result, the optimal 309 quantization can be obtained by solving: 310

$$\gamma^* \boldsymbol{B}_{\boldsymbol{W}}^* = \mathcal{B}_{det}(\widehat{\boldsymbol{W}}_{std}) \ll s^*$$
(10)

where $\ll \gg$ is left or right bit-shift, s^* and \widehat{W}_{std} can be calculated by:

$$s^* = round(\log_2(\frac{\|\widehat{\boldsymbol{W}}_{std}\|_{\mathcal{L}^1}}{n})) \tag{11}$$

$$\widehat{W}_{std} = \frac{\widehat{W}}{\sigma(\widehat{W})}, \, \widehat{W} = W - \bar{W}$$
(12)

where $\sigma(\cdot)$ denotes the standard deviation and \overline{W} is a matrix whose elements are all mean value of weight W. LPB directly binarize the representations using the deterministic binarization function, i.e., $B_x = \mathcal{B}_{det}(x)$. Hence, the operation between the real-valued weights and vectors is reformulated as follows: 316

$$Wx = (B_W \odot B_x) \ll s$$
⁽¹³⁾

where \odot denotes the *XNOR* and *popcount* operation between binary codes.

318 4.2.2 Backpropagation

In this part, we describe how to backpropagate the gradients through the binarization function. We adapt the gradient estimator into our model for better optimization.

Propagation gradients through binarization function It is obvious that the binarization 321 function has zero derivative almost everywhere, which leads to the zero gradients of the loss 322 function w.r.t the pre-activations and weights. The trainable variables cannot be updated 323 with zero gradient. Therefore, the model cannot be trained by simple backpropagation, 324 and the estimation of the gradients should be obtained for optimization. Previous studies 325 have investigated how to propagate gradients through stochastic discrete functions. Below 326 we investigate two popular unbiased gradient estimators for binarization function: straight 327 through estimator and REINFORCE estimator [44]. 328

Straight through estimator The straight-through estimator is proposed a simple unbiased gradient estimator. It estimates the derivative of binarization function $\mathcal{B}(\mathbf{h})$ of pre-activation or weight \mathbf{h} as $\mathbf{1}$ (a vector or matrix whose elements are all 1). Let \mathbf{h}^b denote the binarized representation and \mathbf{h} denote the pre-activation before binarization. The straight-through estimation of the gradient of the loss *L* w.r.t the pre-activation \mathbf{h} is thus:

$$g_{h} = \frac{\partial L}{\partial \mathbf{h}} = \frac{\partial L}{\partial \mathcal{B}(\mathbf{h})} \cdot \frac{\partial \mathcal{B}(\mathbf{h})}{\partial \mathbf{h}} = \frac{\partial L}{\partial \mathbf{h}^{b}} \mathbf{1} = g_{h^{b}} \mathbf{1}$$
(14)

This gradient will then be back-propagated to obtain the gradient of quantities (i.e., preactivations or weights) that influence **h**.

REINFORCE estimator The reinforce estimator is proposed in [2] to estimate the expectation of the gradient $\frac{\partial L}{\partial \mathbf{h}}$ of loss *L* with regard to the pre-activation vector or weight **h**. When binarization function $\mathcal{B}(\cdot)$ is stochastic with the probability given by sigmoid, it has been proven that:

$$\mathbb{E}(\frac{\partial L}{\partial \mathbf{h}}) = \mathbb{E}[(\mathcal{B}(\mathbf{h}) - \sigma(\mathbf{h}))(L - c)]$$
(15)

where σ is the sigmoid function and *c* is a constant vector. To minimize the variance of the estimation, *c* can be chosen as:

$$c = \frac{\mathbb{E}[(\mathcal{B}(\mathbf{h}) - \sigma(\mathbf{h}))^2 L]}{\mathbb{E}[(\mathcal{B}(\mathbf{h}) - \sigma(\mathbf{h}))^2]}$$
(16)

The reinforce estimator can work directly on the weights and pre-activations without actual computation of the gradient. The estimation is obtained by monitoring numerator and denominator during the training process.

Compared with straight through estimator, reinforce estimator is more advanced with better performance in many applications. However, we observe that its performance is not superior than the straight through estimator. On the other hand, straight through estimator helps the model to obtain the gradient faster than the reinforce estimator due to its simplicity. The comparison between these two gradient estimators with regards to the performance is included in Section 5. In practice, we choose straight through estimator for our model in the experiments.

World Wide Web

4.3 Optimization objectives

Existing GNN-based graph embedding approaches provide an end-to-end model, which focuses on the node classification task. Therefore, our model is also learned for the node classification task. Below, we introduce the objective of BGN and the learning process that optimizes the parameters. 356

For the node classification learning, we feed the binarized embedding \mathbf{h}_v^b into the output layer to predict the class label for the node. The predicting probability of label \mathbf{C}_i is written as: 359

$$p(\mathbf{C}_{vk} \mid \mathbf{h}_{v}^{b}) = Softmax_{\zeta}^{k} (\sum_{u \in \eta_{v}} \alpha_{uv}^{L} \mathbf{W}^{L} \mathbf{h}_{u}^{b})$$
(17)

where ζ denotes the number of labels for each node. After obtaining the classification result in (17), we calculate the cross-entropy as the loss for the node classification task. 361

$$L_{class} = -\sum_{v \in \mathcal{V}_{labeled}} \sum_{k=1}^{\zeta} \mathbf{C}_{vk}^{\mathcal{L}} \log(\mathbf{C}_{vk})$$
(18)

where $\mathcal{V}_{labeled}$ is the set of nodes that have label information which are used for training process, $\mathbf{C}_{vk}^{\mathcal{L}}$ is the multi-hot encoding for ground truth classification labels. 363

The gradients will be back propagated via estimator and be applied on the optimization 364 of parameters by the off-the-shelf optimizer during the training process. 365

4.4 Techniques to improve the model

Several techniques are used on binarized graph neural network model to reduce the time 367 and space complexity and improve the performance. Logic operation XNOR between binary 368 values, build-in CPU instruction *popcount* and the masked summation are used to replace 369 the traditional arithmetic operation dot product to reduce time complexity. The Figure 2 is a 370 toy example that introduces the differences between these operations. The balance function 371 is used to make +1 and -1 to be balanced in the embedding vectors which can raise the 372 performance of the GMN. Also, the binary parameters of the neural network and the binary 373 node representations can reduce the space complexity intuitively. 374

4.4.1 XNOR and popcount

4.4.2 Masked summation

The logic XNOR and CPU build-in instruction popcount between binary matrices are used376to replace the dot product between them.377

As shown in Table 2, *XNOR* produces binary value with input of +1 and -1. Instruction 378 popcount is then be employed to count the number of bits that is set to 1. The *XNOR* can be 379 more than one order of magnitude faster than the dot product which can dramatically reduce 380 the time complexity. As mentioned in [4], a 32-bit floating point multiplier costs about 200 Xilinx FPGA slices, whereas a 1-bit *XNOR* gate costs only 1 slice. 382

000

375

366

383

The masked summation is used to replace the dot product between binary matrix and realvalued matrix. The binary matrix will be transformed into the mask matrix with "True" and "False". During the multiplication, the real-valued vector will be masked by the corresponding mask vector, then the positive and negative masked vector are produced with only the 387

World Wide Web

Figure 2 The toy examples of (a) dot product (b) Masked summation and (c) XNOR and popcount instruction

elements at the same position as "True" and "False" on the mask vector. The model calculates the summations of the positive and negative masked vector separately. The subtraction of these two summation results is the result of dot product between the given matrices.

The masked summation can reduce the time complexity of dot product of two matrix. Usually, the time complexity of naive dot product between two real-value matrices $M_1 \in \mathbb{R}^{m \times n}$ and $M_2 \in \mathbb{R}^{n \times d}$ is $\mathcal{O}(mnd)$, while the time complexity of *masked summation* between binary matrix $M_1 \in \{-1, +1\}^{m \times n}$ and real-valued matrix $M_2 \in \mathbb{R}^{n \times d}$ is $\mathcal{O}(nd)$. Theoretically and also in practice, the masked summation can significantly reduce the time complexity of our proposed binarized graph neural network.

397 4.4.3 Balance function

The distribution of +1 and -1 is sometimes unbalanced in the representation vectors. For example, if most pre-activations **h** have *positive* elements, the output graph representation vector of binarization function \mathbf{h}^b will be formed mainly by +1. Then the dot product of two vectors will be *d* which is the dimension of the vectors. This unwanted situation should be avoid because it dramatically lower the effectiveness of the proposed model, especially when the BGN is applied to GMN which requires a great number of dot product between

Input B	Output

-1	-1
+1	-1
-1	+1
	Input B +1 -1 +1 -1

Table 2	XNOR	calculation
	MON	calculation

World Wide Web

representations. As a result, we apply the following balance function to the pre-activations 404 before binarization in order to balance the distribution of *positive* and *negative* elements of 405 pre-activations: 406

$$Balance(\mathbf{h}) = \mathbf{h} - \overline{\mathbf{h}} \tag{19}$$

Where the $\overline{\mathbf{h}}$ is the vector whose elements are all mean value of the pre-activation vector 407 **h**. The balance function ensures that the pre-activation vectors contain almost half *positive* 408 and half *negative* elements, which leads to the balance distribution of +1 and -1 after 409 binarization. 410

4.5 Adapted to Other GNN based models

The proposed binarized graph neural network is a very general framework that can be adapted to other graph neural network-based model to project the real-valued parameters and activations into the binary space to reduce the space and time cost. We introduce how we binarize the state-of-the-art GNN-based model AS-GCN [12] and the graph matching network. 416

4.5.1 Binarization of AS-GCN

AS-GCN is a general framework that is designed for fast representation learning based on graph neural networks such as GCN. Therefore, the binarization of AS-GCN is similar to our proposed BGN. We use deterministic binary function to binarize the parameters and preactivations of AS-GCN. And straight through estimator is employed for back propagation. The binarized model is denoted as BGN-ASGCN in our experiment.

4.5.2 Binarization of GMN

As mentioned above, the time cost of GMN comes mainly from the pair-wise node similarity computation. We utilize the deterministic binarization function (3) on the preactivations and transform the node and graph representations into binary codes such that the XNOR can be applied to replace the dot product. Straight through estimator (14) is used for the back propagation. Furthermore, we noticed that the distribution of +1 and -1 is usually not symmetric which dramatically lower the performance, hence, balance function (19) is employed on the graph representations.

Experiment

We conduct extensive experiments to evaluate the performance of our model for the node 432 classification task on real-world network datasets. We compare the time and space efficiency thoroughly between the proposed model and other baseline models. The case study 434 shows the effectiveness and efficiency brought by our framework on the GNN-based 435 application such as GMN. 436

5.1 Dataset

To facilitate the comparison between our model and the relevant baselines, we conduct the classification experiments on three well-known citation network datasets: **Cora**, **Citeseer** and **Pubmed** [34]. Each dataset contains bag-of-words representations of documents and

- citation links between the documents. Graph G is constructed based on the citation links.
- 442 In the classification task, we only use 20 labeled instances per class for training. The test
- data contains 1000 nodes as in GCN, GAT and AS-GCN. We also include other types of dataset for extensive comparisons. The experiments are also conducted on two social net-
- work datasets: **Facebook** and **wiki-vote** [16] and two air-traffic networks [32]: **Brazil** and
- 446 USA. For social networks, we randomly select 10% and 20% of nodes for training and val-
- idation respectively, and the rest of nodes are used as test set. For air-traffic networks, we
- randomly assign equal number of nodes in training, validation and test sets.
- The details of the datasets are summarized in the Table 3.

450 **5.2 Baseline methods**

- 451 The following GNN-based and binary embedding methods are compared as baselines:
- 452 **GCN** (Graph Convolutional Network) [40] is a semi-supervised neural network method 453 for node classification.
- 454 **GAT** (Graph Attention Network) [40] is a graph neural network model which first 455 exploits the attention mechanism to solve the node classification task.
- 456 AS-GCN (Adaptive Sampling over GCN) [12] is a state-of-the-art method for node clas-
- sification task. AS-GCN aims to increase the scalability of GCN using adaptive sampling.
 The experiments demonstrate that the application of BGN can further reduce the time
 and space complexity of AS-GCN.
- GAT-binary and ASGCN-binary are the models that directly apply sign function on the
 node representations learned by the original version of GAT and AS-GCN. The naively
 binarized representations will be fed into the task-specific layer to learn the classification
 result.
- GAT-tanh and ASGCN-tanh are the models that employ the binarization function *tanh*used by *DeepMind*'s work. *tanh* function is used to binarize the parameters and embedding vectors of GAT and AS-GCN. We clip the value of the parameters and activations
 in both models to make sure that *tanh* can produce "exact" binary codes.
- INH-MF [20] is a MF-based information network hashing algorithm that learns binary
 codes as node embedding which can preserve high-order proximity.
- 470 BANE(Binarized Attributed Network Embedding) [46] is an extension of DNE [37]
- which based on the Weisfeiler-Lehman proximity matrix factorization learning functionto produce binary node representations.
- Besides, we also compared the variants of our proposed BGN with the quantization methods introduced in Section 4.2.1:

- **BGN-x-GAT** and **BGN-x-ASGCN** are the binarized models of graph attention network 475 and ASGCN using (6) and (7). 476
- **BGN-lpb-GAT** and **BGN-lpb-ASGCN** are the binarized models of graph attention network and ASGCN using Libra Parameter Binarization (LPB). 477

5.3 Experiment setup

479

496

499

For the performance experiment, we evaluate the models with the same bit-width represen-
tations. For the experiment of inference efficiency, the embedding dimension of our method
and other baseline methods are all set to 64. During training process, the whole graph can be
seen, but only a few nodes are labeled while most nodes have no label information. We put
all nodes information in one training phase due to the need of calculation for graph attention
description480
481
482all nodes information in one training phase due to the need of calculation for graph attention
485481
484

For this classification task, we report the average accuracy of the evaluated GNN-based embedding approaches after ten independent runs using the accuracy metric introduced in [15, 40]. Because INH-MF and BANE only produce the binary embedding vectors but have no build-in classifier, we employ the one-vs-rest logic regression implemented by Liblinear [7] to obtain the classification result of the networks, in which 90% nodes are labeled. 480

All the experiments were conducted on the server which is running RHEL 7.5 and has4912x 2.4GHz Intel Xeon E5-2680 v4 (14 Cores) CPU, 256GB 2400MHz ECC DDR4-RAM492and 2x NIVDIA Quadro P5000 16GB Graphics Card (GPUs) (2560 Cores). The time cost493of our trained binarized model is evaluated on the CPUs using the *XNOR* and *popcount*494instructions. The time cost of other baseline GNN-based methods is evaluated on GPUs.495

5.4 Classification results

Because our model produces the compact representations for vertices, we compare the 497 performance between our model and other baselines with the same bit width. 498

5.4.1 Comparison among binary embedding methods

We compare the classification results between our model and other binary-valued embedding methods. 501

As shown in the Figure 3, under different embedding dimensions, BGN outperforms all 502 the other binary-valued embedding methods significantly on all three datasets. With the help 503 of the graph neural network, our model can make better use of the graph structured data and 504 feature information and is trained specifically for the node classification task. Therefore, our 505 model outperforms other MF-based binarized graph embedding models by a significantly 506 large margin. In comparison with the naively binarized GAT-binary and ASGCN-binary, our 507 model considers the binary property of parameters and vectors during the training process, 508 hence our model achieves better accuracy. In terms of GAT-tanh and ASGCN-tanh, because 509 tanh function has zero gradient when the output is nearly +1 or -1 and has real-value output 510 when the gradient is not zero. This property determines that *tanh* function is not suitable for 511 binarizing the neural network. When the input values are clipped to produce exact binary 512 parameters and embeddings via *tanh* function, the gradient will be zero which results in 513 the insufficient optimization and worse performance than BGN. Furthermore, the models 514 that are binarized by BGN-x and BGN-lpb achieve better performance than other compared 515 methods. 516

Figure 3 Classification results of three citation network dataset among the binary-valued embedding methods with different embedding dimensions

517 5.4.2 Comparison among the GNN-based methods

We compare our model with other GNN-based methods (GCN, GAT and AS-GCN). All baseline methods produce the real-valued embedding vectors each dimension of which is encoded by at least 32 bits. Compared with these methods, each dimension of the embedding vectors learned by our model is only encoded by 1 bit. As a result, a real-valued 16 dimension vector requires at least 256 bits while a binary vector only requires 16 bits. Figure 4 shows the performance of the models with bit width varies for a single embedding vector.

524 Our model significantly outperforms all the baseline methods with low bit width. When 525 getting more space for the learned representations, our model can still achieve compet-526 itive classification results compared with the state-of-the-art graph neural network-based 527 methods. In conclusion, the performance gap between our model and baselines with large

World Wide Web

Figure 4 Classification results of three citation network dataset among the GNN-based methods with varied bit width for embedding vector

bit-width representations is acceptably small while our model's performance is notably better with the low bit-width representations.

5.5 Comparison of time and space efficiency

In this section, we report the inference time and space efficiency of our model. The inference is the process that produces the classification result when we have already trained the model. Acceleration is brought by the *XNOR* and *popcount* operation with just little sacrifice on the classification performance. In this experiment, we train the binary parameters and activations of our model, then replace dot product operation between binarized matrices by *XNOR* and *popcount* and also replace the dot product between binary matrix and real-valued matrix by masked-summation during the inference process.

Tables 4 and 5 report the experiment results. GAT-binary, ASGCN-binary, GAT-tanh and 538 ASGCN-tanh require the same size of parameters as their real-valued version since these 539 baslines only binarize the representations of the nodes while keep using the real-valued 540 parameters in the model. Among these models, GAT-binary and ASGCN-binary can be 541 accelerated by applying the mask summation during inference process, while GAT-tanh and 542 ASGCN-tanh have to perform conventional matrix multiplication since these two meth-543 ods cannot guarantee to produce exact binarized codes as node representations. Our model 544 under the binarized framework is more than one order of magnitude faster than the baseline 545

547 up to $29 \times$ faster and save up to $28 \times$ space compared with the baseline meth

548 5.6 Analysis of binarization

In this section, we introduce the effect of the estimator and binarization level with regard to the space, time and performance. We compare the space, inference time and performance between BGN-GAT and GAT on the Cora dataset. We fix the dimension of embedding vector to 64 for both methods and change the setting of BGN to show the space and time saving compared with the baseline GAT.

Result is shown in Table 6 where BGN^w , BGN^{e} , BGN^{we} and BGN^{wec} mean that the BGN is with weights binarized, embedding vectors binarized, weights and embedding vectors binarized, weights, embedding vectors and attention coefficients binarized based on the graph attention mechanism respectively. We can conclude from the Table 6 that (1) when the weights, activations and attention coefficients are all binarized, the BGN-GAT can save largest space for parameters and the output vectors while holding acceptable classification accuracy. (2) Straight through estimator and reinforce estimator have similar accuracy on

Method	Estimator	Param space	Vec space	Speed up	Accuracy
GAT	N/A	1×	1×	1×	84.0%
BGN^w	STE	1/28	1×	3.7×	80.5%

World Wide Web

the node classification task. Therefore, we choose the STE for our model in the above experiments because of its simplicity and certainty. (3) Compared with original GAT, BGN-GAT can save $28 \times$ space for model parameters, $19 \times$ space for activations and achieve $19 \times$ speed up. 563

5.7 Case study

565

In this section, we investigate how binarized graph neural network improve the time effi-566 ciency of the GNN-based applications such as GMN. Because GMN needs to compute the 567 pair-wise dot product between node and graph embedding vectors, the time consumption is 568 extremely high when the number of nodes in each graph goes up. However, with the binary 569 representations, we can apply XNOR between binary vectors to replace the dot product, 570 which will alleviate the time complexity problem significantly. The following experiment 571 results will introduce the performance and time complexity of GMN with binary node and 572 graph representations compared with the origin version. The graph similarity will then be 573 used for the graph matching task. 574

- **Experiment Setup** We follow the experiment setting of [18] to test the performance of 575 Binarized GMN. The training data is generated by sampling binomial graphs G_1 with n 576 nodes and edge probability p [6]. Then the positive example G_2 is generated by randomly 577 substituting k_p edges from G_1 with new edges and negative example G_3 is generated by 578 substituting k_n edges from G_1 , where $k_p < k_n$. In the experiment, we set $k_p = 1, k_n = 2$ 579 and p = 0.2. We also set the hamming similarity between vectors as loss function, which 580 is more suitable for the binary-valued vectors as the loss function to train the model. The 581 model needs to predict a higher similarity score for positive pair (G_1, G_2) than negative 582 pair (G_1, G_3) . The evaluation metric remains the same: (1) pair AUC - the area under 583 the ROC curve for classifying pairs of graphs as similar or not on a fixed set of 1000 584 pairs and (2) triplet accuracy - the accuracy of correctly assigning higher similarity to the 585 positive pair in a triplet than the negative pair on a fixed set of 1000 triplets. 586
- Inference time and Graph Matching PerformanceWe report the graph matching587accuracy and inference time of the binarized and original GMN with regards to the number of nodes in each graph. The default setting in GMN is 20 nodes per graph, which is588quite small for real-world networks. We set the number of nodes in one graph from 20590to 160 and keep other settings the same as described above to evaluate the performance591and inference time. The dimensions of node and graph representations are set to 32 and59364 respectively.593

As shown in Figure 5, the inference of BGN-GMN is significantly faster. This is because of the fact that the similarity computation (pair-wise dot product) between node representations of two graphs mainly accounts for the time complexity of GMN. Under the same dimension of node and graph embedding vectors, BGN-GMN is up to $21 \times$ faster than the baseline model in terms of the inference time with the help of the replacement of dot product by fast operations such as *XNOR* and *popcount* between binary vectors. 600

In terms of graph matching task, the original version of GMN has better performance 601 when the number of nodes in each graph is small. However, when the number of nodes 602 gets larger, the pair AUC and triplet accuracy will both decay. When the number of 603

World Wide Web

Figure 5 The performance of graph matching and inference time for GMN and BGN-GMN w.r.t the number of nodes per graph

nodes is more than 60, the real-valued representations cannot tell the similarity difference 604 between the graphs. Hence, the model is not able to learn the different similarity scores 605 for positive and negative pairs of graphs with the hamming similarity metric. However, 606 with the help of binarization and balance function, the binary representations still hold 607 an acceptable and more robust performance for the graph matching task. This is due to 608 the fact that the binarized model produces *true* binary representations for the calculation 609 of hamming loss and is designed for the graph matching task specifically on hamming 610 space. 611

Parameter Sensitivity Analysis We compare the performance of binarized and original version GMN to show the effect of dimension for node and graph embedding vectors. We set the number of nodes in each graph n = 30 for this comparison. We change the dimension of graph embeddings produced by two models to ensure them to produce the same bit-width embedding vectors and keep the other settings as the same to compare the performance of two models.

The result is included in Figure 6a. We can find that the binary graph representations tend to have better performance when they are low bit-width and have similar accuracy when the bit-width for the representations getting larger. The binary representations have more robust performance compared with the baseline model when the dimension of embedding varied.

The node representations' binarization is more important than the graph representations' because the dot product operation is mainly conducted between the node representations which costs plenty of time. The performances of GMN and BGN-GMN are compared under different bit-width for the node embedding vectors by varying the dimensions.

As shown in Figure 6b, the result for the pair-wise AUC is similar between the binary 626 and the real-valued node embedding vectors, but BGN-GMN holds a better performance 627 with low bit-width representations. As for the triplet graph accuracy, the binary embed-628 ding vector achieves better performance with short code length and similar accuracy as 629 real-valued node embedding with long code length. These results indicate that the binary 630 representations are much better for the comparison between two graphs under low bit-width 631 circumstances. In line with the result of the binary graph embedding vectors, the binary 632 node embedding vectors also have more robust performance compared with the real-valued 633 node representations. 634

6 Conclusion

We present a model focused on the challenging problem of seeking binary representations of 636 network embeddings using a compact neural network structure. We proposed a novel bina-637 rized graph embedding method, namely BGN, that has binarized parameters and enables 638 GNNs to learn discrete embedding. The binarized neural network can reduce the memory 639 and time cost of the GNN such that increases the scalability of GNNs. BGN can be naturally 640 integrated into other GNN models to enhance the performance of the model such as graph 641 matching network in terms of the inference time and space consumption. External experi-642 ment also illustrates that BGN can increase the time efficiency while holding competitive 643 accuracy. 644
