61 **Abstract**

62 Trace organic contaminant (TrOC) studies in Australia have focused on wastewater effluents,
63 leaving a knowledge gap of their occurrence and risk in freshwater environments. This study

64 measured 42 TrOCs including industrial compounds, pesticides, pharmaceuticals and
65 personal care products (PPCPs) by liquid chromatography tandem mass spectrometry at 73
66 river sites across Australia quarterly for one year. TrOCs were found in 92% of samples, with
67 a median of three compounds detected per sample (maximum 18). The five most commonly
68 detected TrOCs were the pharmaceuticals salicylic acid (82%; max = 1,530 ng/L),
69 paracetamol (also known as acetaminophen; 45%; max = 7,150 ng/L) and carbamazepine
70 (27%; max = 682 ng/L), caffeine (65%; max = 3,770 ng/L), and the flame retardant *tris*(2-
71 chloroethyl) phosphate (TCEP; 44%; max = 184 ng/L). Pesticides were detected in 28% of
72 the samples. To determine the risk posed by the detected TrOCs to the aquatic environment,
73 hazard quotients were calculated by dividing the maximum concentration detected for each
74 compound by Predicted No Effect Concentrations (PNEC). Three of the 42 compounds
75 monitored (the pharmaceuticals carbamazepine and sulfamethoxazole and the herbicide
76 simazine) had a hazard quotient >1 suggesting that they may be causing adverse effects at the
77 most polluted sites. A further 10 compounds had hazard quotients >0.1 indicating a potential
78 risk; these included four pharmaceuticals, three personal care products and three pesticides.
79 Most compounds had hazard quotients significantly <0.1. The number of TrOCs measured in
80 this study was limited and further investigations are required to fully assess the risk posed by
81 complex mixtures of TrOCs on exposed biota.

82 **Keywords**

83 Hazard quotient; micropollutant; surface water; TrOC; water quality.

84

85 **1. Introduction**

86 With the human population surpassing seven billion, freshwater demand for municipal,
87 agricultural and industrial use has never been higher. There are over 100,000 registered

88 chemicals in the European Union (EU) alone (Schwarzenbach et al. 2006) and recent
89 improvements in analytical chemistry methodologies have enabled the study of trace organic
90 contaminants (TrOCs) in freshwater at relevant environmental concentrations. There are over
91 4,000 pharmaceutical and personal care products (PPCPs) on the market (Boxall et al. 2012)
92 and studies on their fate in the environment are lacking, along with an understanding of the
93 nature and toxicity of their environmental transformation products (Brausch and Rand 2011,
94 Fent et al. 2006). This is particularly the case in Australia (reviewed in Santos et al. 2010).
95 A 2002 study detected 76 out of 95 wastewater-associated TrOCs monitored in 139 streams
96 across the United States (US; Kolpin et al. 2002). A follow up study targeted 74 groundwater
97 and surface water sources of drinking water for 100 TrOCs and found at least one TrOC at
98 92% of the sites (Focazio et al. 2008). These two nation-wide studies established TrOC
99 concentration patterns across US impacted waterways. The first EU-wide assessment of
100 TrOCs covered 122 surface water sites across 27 countries where 90% of the samples had a
101 detection of at least one of the target TrOCs (Loos et al. 2009).

102 Australian research on TrOCs has predominantly focused on wastewater treatment plant
103 (WWTP) processes and effluent rather than the receiving environment (Braga et al. 2005a, b,
104 Chapman 2003, Coleman et al. 2008, Leusch et al. 2006, Mispagel et al. 2009, Williams et al.
105 2007, Ying et al. 2009). Khan and Ongerth (2004) used fugacity models to predict WWTP
106 effluent concentrations of at least 50 pharmaceuticals and prioritised subsequent efforts for
107 analytical investigation. A recent study of 39 Victorian WWTP effluents confirmed the
108 presence of various TrOCs including PPCPs, pesticides, food additives and alkylphenols
109 (Allinson et al. 2012). Concentrations were typically in the 1-1000 ng/L range but some
110 compounds like carbamazepine were found above this range. Another study detected
111 antibiotics in WWTP effluents at concentrations up to 3,400 ng/L, while rivers typically had
112 low ng/L concentrations (but a maximum of 2,000 ng/L) (Watkinson et al. 2009).

113 For this study, 285 grab water samples were collected from 73 river sites across Australia
114 every quarter over a one-year period. Samples were concentrated using solid phase extraction
115 (SPE) and specific TrOCs analyzed by liquid chromatography tandem mass spectrometry
116 (LC-MS/MS). The objective was to assess the risk of TrOCs to the environment by
117 determining their concentrations in impacted freshwater environments to better understand
118 the relationship between land-use activities and aquatic contamination.

119

120 **2. Experimental section**

121 *2.1. Site selection*

122 Sites were selected after extensive consultation with academics, regulators and water industry
123 partners. Sample locations consisted of 19 sites each in New South Wales (NSW),
124 Queensland (QLD), and Victoria (VIC), 10 sites in Western Australia (WA), and three sites
125 each in the Northern Territory (NT) and South Australia (SA) (Fig. 1). Sampling locations
126 (Fig. 1) reflect the fact that most Australians live in close proximity to the coast and the
127 center of the continent receives little rain. Sites were categorized based on the primary land-
128 use activity upstream in the catchment. Sites were rarely influenced by just one land-use and
129 so the dominant land-use dictated site categorization. Detailed catchment information can be
130 found in SI Table S1. Freshwater aquatic environments in catchments with agricultural,
131 industrial, residential and WWTP activities were selected, along with sites in catchments with
132 less anthropogenic influences (*i.e.*, “undeveloped” or “reference” sites) from each
133 state/territory (Table 1). QLD consisted of five undeveloped sites, while NSW and VIC both
134 had three. NT, SA and WA had only one undeveloped site per territory/state. Other land-uses
135 had to be prioritized due to a smaller number of sampling locations.

136

137 *[INSERT FIG 1 HERE]*

138

139 *[INSERT TABLE 1 HERE]*

140

141 *2.2. Water sampling*

142 Grab river water sampling started at the project commencement and samples were obtained
143 every three months, in Autumn (May 2011), Winter (August 2011), Spring (November 2011)
144 and Summer (February 2012) from each site (with the exception of NT sites, which were
145 only sampled twice, due to in-kind service personnel relocation) (Table 1). Two solvent-
146 rinsed 1 L amber glass bottles were submerged to approximately 20-30 cm depth in fast
147 flowing water as far towards the centre of the channel as possible from the water's edge in
148 order to collect 2 L grab water samples. To prevent biological degradation, 1.5 mL of 12 M
149 HCl (Merck, Victoria, Australia) was added to each bottle to lower the pH to approximately
150 2. Samples were packaged with ice blocks and sent by overnight courier to the laboratory for
151 solid-phase extraction (SPE). Geographic location and budgetary constraints made field
152 blanks unfeasible; however, one laboratory blank was generated for each sampling event.

153

154 *2.3. General water quality parameters*

155 Basic water chemistry (dissolved oxygen, electrical conductivity, pH, temperature) was
156 measured in the field for each sample prior to acidification (SI Table S2). To minimize risk of
157 contamination, a small volume of water from each sample was decanted into a small vial for
158 determination of nitrate and nitrite concentrations with Hach AquaChek Nitrate Nitrite strips
159 (Notting Hill, Australia). Total chlorine, free chlorine, total hardness, total alkalinity and pH
160 were then measured using Hach AquaChek 5-in-1 strips (Notting Hill, Australia) following
161 the manufacturer's instructions (SI Table S2), and the decanted sample was discarded.

162 Stream flow data were not available at the time of sampling; however, rainfall (and
163 atmospheric temperature) data were obtained for one week prior to sampling (SI Table S2).

164

165 *2.4. Solid-phase extraction (SPE)*

166 Upon arrival in the laboratory, water samples were adjusted to precisely pH 2 using 12 M
167 HCl and extracted within 24 h. Samples were vacuum filtered through 2 µm glass fibre filters
168 (47 mm diameter; Millipore, Kilsyth, Australia). One L of sample was passed through a
169 preconditioned SPE cartridge (Oasis HLB SPE cartridges; 500 mg sorbent, 6 cc; Waters,
170 Rydalmere, Australia) at 10 mL/min. Cartridges were pre-conditioned with 2× 5 mL of
171 acetone: hexane (1: 1) (analytical reagent grade; Merck, Victoria, Australia) followed by 2× 5
172 mL methanol (analytical reagent grade; Labscan, Thailand) and finally 2× 5 mL distilled
173 water. After passing the full water sample, the SPE cartridges were dried under vacuum at 20
174 mmHg for 2 h (or until dry). Dried cartridges were wrapped in aluminium foil and stored at
175 4°C until elution (up to two weeks). A polar fraction was eluted with 2× 5 mL methanol and a
176 non-polar fraction was eluted with 2× 5 mL acetone: hexane (1: 1). This was repeated for the
177 second 1 L bottle. Fractions from both cartridges were combined and evaporated under
178 nitrogen until dry and immediately reconstituted into 1 mL methanol for chemical analysis.
179 One laboratory blank was generated for each sampling event.

180

181 *2.5. Liquid chromatography*

182 TrOCs were selected for monitoring based on their occurrence in WWTP effluents and
183 environmental waters, availability of deuterated standards and previously established
184 methods. Analytes were separated using an Agilent (Palo Alto, CA, USA) 1200 series high
185 performance liquid chromatography (HPLC) system equipped with a 150 × 4.6 mm, 5 µm
186 particle size, Luna C18(2) column (Phenomenex, Torrence CA, USA). A binary gradient

187 consisting of 5 mM ammonium acetate in water (A) and 100% methanol (B) at a flow rate of
188 800 $\mu\text{L}/\text{min}$ was used. For ESI positive analyses, the gradient was as follows: 10% B held for
189 0.50 min, stepped to 50% B at 0.51 min and increased linearly to 100% B at 8 min, then held
190 at 100% B for 2 min. For ESI negative analyses, the gradient was as follows: 10% B held for
191 0.50 min, stepped to 60% B at 0.51 min and increased linearly to 100% B at 8 min, then held
192 at 100% B for 3 min. A 5 min equilibration step at 10% B was used at the beginning of each
193 run. For APCI analysis the eluents consisted of milli-Q grade water (A) and 0.1% v/v formic
194 acid in methanol with the following ramp at a flow rate of 700 $\mu\text{L}/\text{min}$: 60% B held for 5
195 min, increased linearly to 100% B at 20 min, then held at 100% B for 3 min. A 3 min
196 equilibrium step preceded injection. An injection volume of 10 μL was used for all methods.
197 Analytical methods using electrospray ionization (ESI) were based on Vanderford and
198 Snyder (2006).

199

200 2.6. *Mass spectrometry*

201 Mass spectrometry was performed using an API 4000 triple quadrupole mass spectrometer
202 (Applied Biosystems, Foster City, CA, USA) equipped with a turbo-V ion source employed
203 in both positive and negative electro-spray modes. Using multiple reaction monitoring
204 (MRM), two mass transitions for all but three of the analytes were monitored for unequivocal
205 confirmation. One mass transition for the labeled internal standard was monitored. Only the
206 first transition was used for quantification. Relative retention times of the analyte and
207 isotopically labeled internal standard were also monitored to ensure correct identification. A
208 table of transitions can be found in the Supplementary Information (SI Tables S3 and S4).

209

210 2.7. *Calibration and limits of quantification*

211 Standard solutions of all analytes were prepared at 1, 5, 10, 50, 100, 500 and 1000 ng/mL. A
212 relative response ratio of analyte/ internal standard over a 1–1000 ng concentration range was
213 generated enabling quantitation with correction for losses due to ion suppression. All
214 calibration curves had a correlation coefficient of 0.99 or better. The limits of quantification
215 (LOQs) were determined as an s/n ratio greater than 10.

216

217 *2.8. Statistical analysis*

218 When required, statistical analysis was performed using the Kruskal-Wallis nonparametric
219 test, followed by Dunn's multiple comparison test, on Prism 5 software (GraphPad Software,
220 California, USA).

221

222 **3. Results and discussion**

223 *3.1. Chemical analysis*

224 The monitored TrOCs were found in 92% of samples, with a median of three compounds
225 detected per sample (maximum of 18). In contrast, Kolpin et al. (2002) reported a median of
226 seven chemical detects per sample and a maximum of 38 (out of 95) in a study that
227 investigated many overlapping chemical classes. Focazio et al. (2008) indicated that a median
228 of four chemicals detected per sample, with a maximum of 31 (out of 100) in surface water
229 and groundwater. These studies used LC-MS with detections typically between 10-500 ng/L.
230 The most chemically diverse sample had 45% of the targeted compounds compared to 40%
231 found in a US study (Kolpin et al. 2002). However, a subsequent US-based surface water and
232 groundwater study reported 63% of targeted TrOCs present in the most chemically complex
233 sample (Focazio et al. 2008). Overall, the six most frequently detected compounds in this
234 study were salicylic acid (82%), caffeine (65%; not analyzed in Spring sampling),

235 paracetamol (also known as acetaminophen; 45%; not analyzed in Spring sampling), TCEP
236 (44%), carbamazepine (27%) and triclosan (25%). Four compounds were detected at least
237 once at concentrations in excess of 1,000 ng/L: paracetamol (7,200 ng/L), simazine (3,900
238 ng/L), caffeine (3,800 ng/L) and salicylic acid (1,500 ng/L).

239

240 *[INSERT FIG 2 HERE]*

241

242 *[INSERT TABLE 2 HERE]*

243

244 *[INSERT TABLE 3 HERE]*

245

246 *3.1.1. Land-use*

247 The analytical methods were initially developed for wastewater contaminants such as
248 pharmaceuticals and personal care products (PPCPs). Of the five land-uses targeted, samples
249 collected downstream of WWTPs (n=50 out of 285) had the highest median number of
250 detections with 7 chemicals per sample (average = 6.5) although this was not significantly
251 different (Kruskal-Wallis test; $p>0.05$) from industrial, residential, or agricultural samples.
252 Industrial (n=28), residential (n=74) and agricultural (n=80) samples had medians of 6, 4 and
253 2 TrOCs per sample, respectively (averages of 6.2, 4.3 and 2.6 TrOCs respectively). Finally,
254 undeveloped sites had the lowest number of TrOCs with an average of 1.5 per sample
255 (median = 1); this value was significantly different (Kruskal-Wallis test; $p<0.05$) from other
256 land-uses. These results indicate that TrOCs are widespread across land-uses and not simply
257 in rivers receiving WWTP discharges. This may be due to the presence of septic tank
258 systems, leaking sewer lines, the result of combined sewer overflows into waterways

259 following intense wet weather events, or some other unknown source. There is clearly a need
260 for further research investigating TrOCs from other land-uses activities.

261 Fig. 2 (top) indicates that the top five most frequently detected compounds did not vary
262 greatly across the different land-uses. The most frequently detected TrOCs were: salicylic
263 acid, caffeine, paracetamol, TCEP, carbamazepine, triclosan, 2-phenylphenol and
264 propylparaben (Tables 2 and 3). Of those, salicylic acid (64-100%) and caffeine (34-90%)
265 were in the top five compounds for all land-use categories (Fig. 2, top). Caffeine is a common
266 wastewater contaminant and has occasionally been used as a marker compound for human
267 wastewater (Metcalf et al. 2003). The prevalence of caffeine and PPCPs suggests
268 widespread (but low) wastewater pollution, from an unknown source(s), possibly septic tank
269 leakage, or sewage overflow during heavy rainfall, which was common in the sampling
270 period (SI Table S2).

271

272 3.1.2. Location

273 Geographic location (Fig. 1, SI Table S2) was used to sort number of TrOCs per sample by
274 Australian state or territory. Samples from NT (n=6) had the highest average number of
275 detections per sample (6.5 compounds per sample). NSW (n=76) had 4.4, WA (n=40) had
276 4.3, SA (n=12) had 4.2, and VIC (n=76) had 4.1 detections per sample. QLD samples (n=75)
277 had the lowest national average with 2.7 compounds detected per sample.

278 Salicylic acid was the most frequently detected compound in each state (Fig. 2, bottom) and
279 detection frequencies varied from 61% in QLD to 100% in SA. It was interesting to see that
280 salicylic acid was one of the most commonly detected compounds despite its relatively high
281 LOQ.

282

283 3.1.3. Seasonal and land-use trends

284 Qualitative assessment of the dataset indicated that most analytes had similar frequencies of
285 detection throughout all four sampling events with a few exceptions (Table 2). Primidone
286 was detected more frequently in Autumn (May-2011) and Spring (Nov-2011), compared to
287 Winter (Aug-2011) and Summer (Feb-2012). Phenytoin was found consistently in Autumn,
288 Winter and Spring (11, 15 and 13 times, respectively), but not once in Summer.
289 Propylparaben was detected 23 times in Spring, but not as often in other sampling events (0
290 times in Autumn; 3 times in Winter; 8 times in Summer). The biocide 2-phenylphenol was
291 only identified twice each in Autumn and Winter, seven times Spring, and 27 times in the
292 Summer. Australia, a continent the size of Europe, experiences vast climatic and seasonal
293 differences between states/territories and even between sites within states/territories.
294 Temperature can significantly influence WWTP removal efficiencies of TrOCs (Ternes et al.
295 1999), and rainfall can impact their dilution in receiving environments (Ternes 1998).
296 Analysis of chemical data sub-divided by land-use did not indicate any trends. Sites were
297 categorized based on the most influential point (*e.g.* WWTP) or non-point sources (*e.g.*
298 agricultural, industrial, or residential) and many had influence from multiple land-use
299 categories. The data suggest that the water quality does not necessarily reflect the dominant
300 proximal land-use influence.

301

302 3.1.4. *Pharmaceuticals.*

303 Six pharmaceuticals were detected in more than 10% of samples: salicylic acid (82%),
304 paracetamol (45%), carbamazepine (27%), primidone (14%), phenytoin (14%) and
305 gemfibrozil (11%). Nine pharmaceuticals were never detected (Table 2) and paracetamol and
306 salicylic acid were detected at concentrations above 1,000 ng/L.
307 Salicylic acid, the most frequently detected compound, is an important metabolite of
308 acetylsalicylic acid (aspirin), but is also a plant hormone and can be found in many species,

309 most notably in willow tree bark (Krantz et al. 2010, National Center for Biotechnology
310 Information 1999). Willows are a pest species in many Australian waterways and may partly
311 explain the broad presence of salicylic acid in this study. Salicylic acid is relatively non-toxic
312 to aquatic wildlife with a predicted no effect concentration (PNEC) usually ranging from
313 60,000 - 170,000 ng/L (Schowanek and Webb 2002, Wang et al. 2010), and the
314 concentrations reported here represent a negligible risk. Many metabolites and degradation
315 products exhibit toxicological effects (Lambropoulou and Nollet, 2014), so further research
316 into these chemical products is required.

317 Paracetamol was detected in 45% of the samples, with a maximum of 7,150 ng/L (the highest
318 concentration in this entire study). In two USA studies, maximum concentrations ranged
319 from 160-10,000 ng/L (Focazio et al. 2008, Kolpin et al. 2002). With a PNEC of 9,200 ng/L
320 (Schowanek and Webb 2002), our data suggests that paracetamol represents a low risk in
321 Australian rivers, although it should be highlighted that the highest concentration detected
322 provided only a narrow margin of safety (Table 3).

323 The next most common pharmaceutical was carbamazepine, an anticonvulsant, with a
324 frequency of 27% and a maximum of 682 ng/L (Table 3). In a USA surface water and
325 groundwater study, the frequency of detection was 22% and the maximum concentration was
326 200 ng/L (Focazio et al. 2008). However, in an EU-wide study of surface waters,
327 carbamazepine was detected more frequently (95%) with a maximum concentration ~20×
328 higher (Loos et al. 2009). Carbamazepine was one of five most frequently detected
329 compounds in each land-use category, except for undeveloped. It was found most commonly
330 in NSW and VIC. The PNEC for carbamazepine is 500 ng/L (Agerstrand and Ruden 2010),
331 suggesting that while there is little cause for concern in most situations, carbamazepine may
332 pose a risk to the receiving environment at some sites (carbamazepine was above 500 ng/L in
333 five out of 285 measurements, *i.e.*, 1.7% of samples). Phenytoin (an antiepileptic also known

334 as dilantin) and primidone (an anticonvulsant) had maximum concentrations of 145 and 259
335 ng/L, respectively (Table 3). In four USA streams, concentrations of phenytoin ranged from
336 3.7–391 ng/L (Snyder et al. 2007), while the maximum concentration in Japanese river water
337 was 51 ng/L (Komori et al. 2013). Primidone was found in 10 German rivers at
338 concentrations ranging from 10–594 ng/L, but typical concentrations were >300 ng/L
339 (Hummel et al. 2006). In Japan, primidone was detected with a maximum concentration of 38
340 ng/L (Komori et al. 2013). Both phenytoin and primidone are relatively non-toxic to aquatic
341 organisms with PNECs of >100,000 ng/L (Komori et al. 2013), suggesting that the
342 concentrations found in this study are unlikely to be of environmental concern.

343 Gemfibrozil (an antiepileptic; LOQ = 5 ng/L) had a maximum concentration of 213 ng/L and
344 a detection frequency of 11% (Table 3). In comparison, it was detected 3.5% of the time in
345 one US-wide study (with a maximum concentration of 790 ng/L; LOQ = 15 ng/L) (Kolpin et
346 al. 2002), and not at all in a follow-up study (LOQ = 15 ng/L; Focazio et al. 2008). However,
347 gemfibrozil was found more frequently in a European study (35%; LOQ = 1 ng/L), which
348 also reported a higher maximum concentration of 900 ng/L (Loos et al. 2009). While the
349 maximum concentration is less than in other studies, the detection frequency is in a similar
350 range. With a PNEC of 1,000 ng/L (Wang et al. 2010), the concentrations detected here
351 represent negligible risk.

352 Sulfamethoxazole, an antibiotic often used in combination with trimethoprim (another
353 antibiotic), was detected in nine percent of samples, with a maximum concentration of 67
354 ng/L (Table 3). Four samples had concentrations that exceeded the PNEC of 26.8 ng/L
355 (Agerstrand and Ruden 2010), while two additional samples were close. Further effects
356 monitoring at the most polluted sites would help assess the environmental risk of
357 sulfamethoxazole.

358 Although trimethoprim was only detected in 5% of samples, it was present at the sixth overall
359 highest concentration (657 ng/L; Table 3). It was detected more frequently (12.5%) and had a
360 higher maximum concentration of 710 ng/L in a US study (Kolpin et al. 2002). However,
361 another US study had a much lower maximum concentration (20 ng/L) (Focazio et al. 2008).
362 With a comparatively high PNEC of 180,000 ng/L (Halling-Sorensen et al. 2000), the
363 concentrations of trimethoprim detected here are unlikely to cause direct environmental
364 effects, however indirect antibiotic resistance could be a potential problem.

365

366 3.1.5. Personal care products (PCPs)

367 Caffeine was the most commonly detected PCP, occurring in 65% of samples, followed by
368 triclosan (25%) and propylparaben (12%). Caffeine was the second most common TrOC in
369 this study (median = 19 ng/L) and had the third highest reported concentration overall (3,770
370 ng/L; Table 3). The maximum concentration was measured in a NSW industrial sample.
371 There were seven other samples with caffeine concentrations above 1,000 ng/L; four
372 residential, three industrial and one WWTP samples. The maximum concentration of caffeine
373 falls between that reported in Focazio et al. (2008) (270 ng/L) and Kolpin et al. (2002) (6,000
374 ng/L). All three mentioned maximums fall significantly short of 39,813 ng/L reported in a
375 European surface water sample (Loos et al. 2009). The frequency of detection for caffeine
376 corresponded closely with that reported in Kolpin et al (2002) (71%). With a PNEC for
377 caffeine of 5,200 ng/L (Komori et al. 2013), caffeine generally poses a low risk, although it
378 should be noted that some of the data points above 1,000 ng/L only leave a slim margin of
379 safety.

380 Triclosan, a widely used broad spectrum antibacterial compound, was the second most
381 commonly detected PCP (25%), with a maximum concentration of 87 ng/L. Kolpin et al.
382 (2002) detected triclosan in 57% of samples with a maximum concentration of 2,300 ng/L

383 and a median concentration of 140 ng/L. Triclosan was also found in wild fish in WWTP
384 effluent receiving environments in Sweden at concentrations up to 0.90 mg/kg fresh weight
385 of bile (Adolfsson-Erici et al. 2002). New evidence suggests that the risk from exposure to
386 triclosan could be underestimated and as such, the PNEC of 500 ng/L (Perez et al. 2013) may
387 not be adequate. For instance, triclosan was found to negatively affect larval fathead minnow
388 (*Pimephales promelas*) swimming performance at 151 ng/L, an exposure concentration less
389 than twice the maximum concentration reported herein (87 ng/L; Table 3; Cherednichenko et
390 al. 2012). Drury et al. (2013) reported that sediment triclosan concentrations (a maximum
391 concentration of 107 ± 18 ng/g) were directly proportional to the relative abundance of
392 resistant bacteria. In light of this information, some triclosan concentrations in Australian
393 rivers may pose considerable risk to aquatic organisms.

394 Propylparaben which is both a natural substance and a PCP, was the third most commonly
395 detected PCP (12%) with a maximum concentration of 218 ng/L (Table 3). The maximum
396 concentration reported is much less than that found in Spanish surface waters (32,000 ng/L)
397 (Regueiro et al. 2009), while another Spanish study did not detect propylparaben in surface
398 waters (<5 ng/L) (Pedrouzo et al. 2009). A UK study reported a maximum concentration of
399 11 ng/L in surface waters (Kasprzyk-Hordern et al. 2008). With a PNEC of approximately
400 20,000 ng/L (Yamamoto et al. 2011), the risk of propylparaben to the Australian aquatic
401 environment appears negligible.

402 Triclocarban, used as an anti-bacterial and anti-fungal disinfectant in soaps and other
403 household products, was detected in one percent of the samples, with a maximum
404 concentration of 58 ng/L. A PNEC of 190 ng/L was recently derived for triclocarban (Tamura
405 et al. 2012). A LOEC of 130 ng/L (NOEC of 60 ng/L) was previously reported for
406 *Mysidopsis bahia* reproduction rate (U.S. Environmental Protection Agency 2008). There is
407 limited information about the occurrence of triclocarban in the environment in general,

408 compared to triclosan. Halden and Paull (2005) predicted mean and median concentrations of
409 213 and 109 ng/L, respectively, in US streams, which warrants further chemical monitoring
410 efforts.

411 DEET was analyzed but results were not presented due to concerns that some LC-MS/MS
412 methods, including ours, may overestimate DEET concentrations due to an unidentified
413 natural substance that is being incorrectly measured as DEET (Snyder, pers. comm.). A more
414 robust chemical analysis methodology for DEET may be required to accurately quantify this
415 compound in the environment.

416

417 *3.1.6. Industrial compounds*

418 The flame retardant TCEP was the only industrial compound examined. TCEP was detected
419 in 44% of samples, with a maximum concentration of 184 ng/L (detected in a SA sample
420 downstream of a WWTP; Table 3). Similarly, Kolpin et al. (2002) detected TCEP in 60% of
421 samples, but reported significantly higher maximum and median concentrations (54,000
422 ng/L, 100 ng/L). Focazio et al. (2008) detected TCEP in 20% of samples, but concentrations
423 were less than the quantification limit (500 ng/L). Mean and maximum concentrations of 203
424 ng/L and 2,019 ng/L, respectively, were found in five German rivers (Quednow and
425 Puttmann 2009). While it was frequently detected, TCEP poses a negligible risk considering
426 its PNEC of 65,000 ng/L (Quednow and Puttmann 2009).

427

428 *3.1.7. Pesticides*

429 Pesticides were not commonly detected in our water samples. As of 2002, simazine (LOQ = 5
430 ng/L) and atrazine (LOQ = 5 ng/L) were the most widely used herbicides in Australia
431 (Radcliffe, 2002), however they were only detected in 14% and 11% of samples,
432 respectively. The fungicide 2-phenylphenol (LOQ = 10 ng/L) was detected in 13% of

433 samples, although it was not among the most frequently used fungicides in Australia
434 (Radcliffe 2002). Linuron (LOQ = 5 ng/L), which has the same mode of action as atrazine
435 and simazine, has also been used frequently in Australia, but was only detected in three
436 percent of samples; predominantly in agricultural samples (66% of detections). Chlorpyrifos
437 (LOQ = 5 ng/L) and diazinon (LOQ = 5 ng/L) have been the most widely used insecticides in
438 Australia (Radcliffe, 2002); but despite its wide use, chlorpyrifos was detected only twice at
439 very low concentrations (5 ng/L) and diazinon was never detected. Trifluralin was not
440 detected either (LOQ = 150 ng/L), despite its wide use as a pre-emergent control for weeds
441 (Radcliffe, 2002). It is, however, important to note that chlorpyrifos, diazinon and trifluralin
442 were only analyzed in the Spring sampling event.

443 Simazine had a maximum concentration of 3,930 ng/L (Table 3), which exceeded the PNEC
444 of 3,200 ng/L derived using the 95th percentile and may pose a risk (ANZECC/ARMCANZ
445 2000). However it should be noted that it was only exceeded in one sampling event. The
446 maximum concentration was also higher than those found in different studies in Australia, the
447 US and Europe. An Australian study of 39 WWTP effluents reported a maximum
448 concentration for simazine of 1,727 ng/L (Allinson et al. 2012). A European survey of river
449 waters reported a detection frequency of 26%, a maximum concentration of 169 ng/L and an
450 average concentrations of 10 ng/L (Loos et al. 2009). An EU ground water survey reported a
451 higher detection frequency of 43% but a lower maximum concentration of 127 ng/L and an
452 average of 7 ng/L (Loos et al. 2010). In a US shallow groundwater study of 1,034 sites,
453 simazine had a detection frequency of 18% and a maximum concentration of 1,300 ng/L
454 (Kolpin et al. 1998), while a surface water study including 151 water samples from 71
455 streams (and five reservoirs) detected simazine in 7 – 47% of samples (depending on sample
456 type) and a maximum concentration of 14,150 ng/L, while median concentrations were all
457 below the reporting limit (<50 ng/L; Battaglin et al. 2003).

458 The maximum concentration for 2-phenylphenol (92 ng/L) occurred in a sample collected
459 downstream of a WWTP in VIC. This concentration was lower than the sole concentration
460 measured from 39 different WWTP effluent samples in the same state (240 ng/L) (Allinson et
461 al. 2012). A PNEC of 900 ng/L was determined using a reproduction test with *Daphnia*
462 *magna* (Bayer 2001), which results in a Hazard Quotient (HQ) of 0.1 for 2-phenylphenol.
463 This indicates that there may be cause for concern at the maximum concentration.

464 Atrazine was detected in 11% of samples, with a maximum concentration of 209 ng/L (Table
465 3). Kolpin et al. (1998) reported a much higher detection frequency (38%) and maximum
466 concentration (3,600 ng/L). In Europe, a detection frequency of 68%, a maximum
467 concentration of 46 ng/L and an average concentration of 3 ng/L were reported in surface
468 waters (Loos et al. 2009). Atrazine was detected in 56% of groundwater samples in Europe
469 with a maximum concentration of 253 ng/L and an average of 8 ng/L (Loos et al. 2010).

470 Atrazine was detected twice in WWTP effluents from across VIC with a maximum
471 concentration of 63 ng/L (Allinson et al. 2012). Interestingly, Australian WWTP effluent
472 contained less atrazine than river waters investigated in this study, again clearly indicating
473 that pesticides are likely to be attributable to other activities (such as agriculture, road
474 maintenance, etc). Atrazine has a PNEC of 13,000 ng/L (ANZECC/ARMCANZ 2000) and as
475 such, the maximum concentration of 209 ng/L is unlikely to be cause for concern, although
476 sampling design did not take into account run-off events, when environmental concentrations
477 could be elevated. Furthermore, there is still a vigorous scientific debate about its potential
478 endocrine effects (APVMA 2008).

479 It should be noted that we only measured a small number of pesticides, and that there is a
480 large and growing body of literature on many different types of pesticides detected in
481 Australian rivers (*e.g.*, Allinson et al. 2012; Church et al. 2004; Davis et al. 2008; Lewis et al.
482 2009; Sanchez-Bayo and Hyne 2014; Schäfer et al. 2011).

483

484 *3.2. Conclusions*

485 A median of three TrOCs out of 42 was detected per sample, with a maximum of 18. The six
486 most frequently detected compounds in this study were: salicylic acid (82%), caffeine (65%),
487 paracetamol (45%), TCEP (44%), carbamazepine (27%) and triclosan (25%). Most
488 pharmaceutical detected were at concentrations posing negligible risk. However,
489 carbamazepine and sulfamethoxazole exceeded their PNECs five and four times each,
490 respectively. Maximum concentrations of other pharmaceuticals (fluoxetine, gemfibrozil,
491 naproxen, paracetamol) and PCPs (caffeine, triclocarban and triclosan) left only small
492 margins of safety when compared to their respective PNECs. The pesticide simazine
493 exceeded its PNEC in one sample, indicating potential risk. Chlorpyrifos, linuron and 2-
494 phenylphenol concentrations were below their respective PNECs, but had thin margins of
495 safety. TCEP was commonly detected but unlikely to be cause for concern.

496

497 *3.3. Limitations and future research*

498 The PNEC values used to calculate Hazard Quotients (HQs) and margins of safety were
499 based on international studies, and it is unclear at this stage whether those levels would
500 protect the unique Australian wildlife. Further work is needed to establish PNECs specific to
501 the Australian environment.

502 The analytical issues with DEET and salicylic acid need to be overcome in the future to
503 determine the actual impact that anthropogenic use of these chemicals have on the
504 environment. This study relied on grab sampling, and further studies with composite or
505 passive sampling techniques may provide a better measure of concentrations over longer time
506 windows.

507 This study measured "only" 42 TrOCs and many more are likely present in the Australian
508 environment, including environmental transformation products. While most compounds were
509 present below PNEC values, their potential for interaction and mixture toxicity needs to be
510 investigated using effects based assessment (*e.g.*, using *in vitro* and *in vivo* techniques).
511 Finally, *in situ* studies at the most polluted sites identified would help determine if the PNEC
512 exceedances reported lead to significant environmental disturbances.

513

514 **Acknowledgment**

515 The authors gratefully acknowledge the assistance of E. Prochazka and T. Teo for their
516 laboratory analysis, and M. Allinson, J. Blackbeard, S. Codi-King, H. Chapman, A. Colville,
517 D. Gale, B. Harper, M. Mortimer, and T. Reitsema for their input in planning and
518 implementation during this project. Sampling could not have been completed without the
519 dedication of many industry partners, whose support we are very grateful for. This study was
520 funded by the Australian Research Council (ARC Linkage scheme LP100100163) in
521 collaboration with Water Research Australia, Sydney Water, Seqwater and Melbourne Water,
522 and supported in-kind by the Queensland Department of Science, Information, Technology,
523 Innovation and the Arts (DSITIA) and the Western Australia Department of Water. P.S. was
524 supported with an Australian Postgraduate Award (Industry) scholarship and Water Research
525 Australia PhD top-up scholarship.

733 **Figure titles -**

734 Figure 1 - Location of sampling sites across mainland Australia. State and territory capitals
735 are depicted by white stars, while black circles represent sampling locations. The population
736 density graph was obtained from the Australian Bureau of Statistics (2012).

737

738 Figure 2. (top) Frequency of detection for the five most detected compounds for each land-
739 use. Salicylic acid and caffeine were the most and second most commonly detected
740 compounds in each land-use. (bottom) Frequency of detection for the five most detected
741 compounds in each state. Salicylic acid and caffeine were again the first and second most
742 detected compounds, respectively, in all six states and territories. Numbers in brackets
743 represent the total number of samples analyzed for the respective compound. "TCEP" =
744 tris(2-Chloroethyl) phosphate.

745 **Tables –**

746

747 Table 1. The number of samples collected during the four separate sampling events
748 and the dominant land-use at each site. WWTP = wastewater treatment plant.

749

Dominant adjoining land-use	Autumn May-11	Winter Aug-11	Spring Nov-11	Summer Feb-12
Agricultural	20	20	20	20
Industrial	7	7	7	7
Residential	19	19	18	18

Table S1. Catchment composition based on primary land-use. Catchment assessments were performed for each sampling site to assess the impact of agricultural, industrial, residential, wastewater treatment plant (WWTP) effluent, and undeveloped inputs at each sampling location. The dominant land-use was used for grouping.

Table S2. Basic water parameters and meteorological data. Ranges reported here are based on four sampling events. pH, water temperature, dissolved oxygen (DO) and electro-conductivity (EC) determined via multi-meter. Nitrate, nitrite, total chlorine, free chlorine, total hardness, total alkalinity, pH (Hach strip) all determined using Hach strips (Section 2.3). Average atmospheric temperature and total precipitation values calculated for the week prior to sampling day (data downloaded for the nearest weather station from the Australian Bureau of Meteorology). “NA” = not available.

Site Number	pH	Water temperature (°C)	Dissolved oxygen (mg/L)	Electro-conductivity (µS/cm ²)	Nitrate (ppm)	Nitrite (ppm)	Total chlorine (ppm)	Free chlorine (ppm)	Total hardness (ppm; CaCO ₃)	Total alkalinity (ppm; CaCO ₃)	pH (Hach strip)	Atmospheric temperature (°C)	Precipitation (mm)
